Numerical results and conclusions

## Extended formulations

## Reformulation involving extra variables

## $\Downarrow$

tighter relations between variables

Ways to obtain

- Variable Splitting (binary or unary expansion)
- Network Flow (Multi-Commodity)
- Dynamic Programming Solver [Martin et al]
- Union of Polyhedra [Balas]
- Polyhedral Branching Systems [Kaibel, Loos]
- ...

## Ways to exploit extended formulations

1. Use a direct MIP-solver approach: size is an issue.
2. Use projection tools: Benders' cuts.
$\rightarrow$ dynamic outer approximation of the formulation
3. Use of an approximation [Van Vyve \& Wolsey MP06]

- Drop some of the constraints
- Aggregate commodities
- Partial reformulation
$\rightarrow$ static outer approximation of the formulation

4. Use (delayed) column generation.
$\rightarrow$ dynamic inner approximation of the formulation

## Column-and-row generation

It is a generalization of the standard column generation (based on the Dantzig-Wolfe reformulation).

Our contributions

- Reviewing of the methodology of the column-and-row generation and presenting it as a generic approach
- Analysis of the interest of the column-and-row generation approach: its good performance is explained by a stabilization effect
- New computational results

## Extended formulation for a subsystem

Original formulation

$$
\begin{aligned}
{[F] \equiv \min \{c x} & \\
A x & \geq a \\
B x & \geq b \\
x & \left.\in \mathbb{Z}_{+}^{n}\right\}
\end{aligned}
$$

## Subsystem

$$
\begin{aligned}
& \mathrm{P} \equiv\{B x \geq b \\
& \left.x \in \mathbb{R}_{+}^{n}\right\} \\
& X=\mathrm{P} \cap \mathbb{Z}^{n}
\end{aligned}
$$

Main assumption
There exists a polyhedron

$$
Q=\left\{H z \geq h, z \in \mathbb{R}_{+}^{e}\right\}
$$

and transformation $T$ s.t. $Q$ defines an extended formulation for $X$ :

$$
\operatorname{conv}(X)=\operatorname{proj}_{x} Q=\left\{x=T z: H z \geq h, z \in \mathbb{R}_{+}^{e}\right\}
$$

## Extended reformulation

Original formulation

$$
\begin{aligned}
{[\mathrm{F}] \equiv \min \left\{\begin{array}{rl}
c x & \\
A x & \geq a \\
B x & \geq \\
x & \left.\in \mathbb{Z}_{+}^{n}\right\}
\end{array}, \begin{array}{rl}
\end{array}\right) }
\end{aligned}
$$

## Extended reformulation

$$
\begin{array}{rll}
{[\mathrm{R}] \equiv \min \{c T z} & & \\
A T z & \geq & a \\
H z & \geq & h \\
z & \left.\in \mathbb{Z}_{+}^{e}\right\}
\end{array}
$$

Special case: Dantzig-Wolfe reformulation

$$
\begin{aligned}
& {[\mathrm{M}] \equiv \min \left\{\begin{array}{l}
\sum_{g \in G} c x^{g} \lambda_{g} \\
\sum_{g \in G} A x^{g} \lambda_{g}
\end{array} \geq a\right.} \\
& \sum_{g \in G} \lambda_{g}=1
\end{aligned}
$$

$$
\left.\lambda \in\{0,1\}^{|G|}\right\}
$$

## Column-and-row generation: a hybrid approach

Alternative to direct resolution by a MIP solver

- Dynamic generation of the variables of [R]: generated in bunch by optimizing over $X$.
- Adding rows that become active.

Alternative to the standard column generation

- Perform the column generation for [M]
- "Project" the master program in [R] (we "split" generated columns into individual variables)

## Example: machine scheduling with a sum criterion

$$
\begin{align*}
& \xrightarrow[\substack{3 \\
S_{3} \\
\begin{array}{c|c|c|}
\hline & 2 & 1 \\
S_{2} \\
\text { (1) (1) (2) (3) (4) (5) (6) }
\end{array} \\
t}]{t} \\
& \min \left\{\sum_{j} c\left(S_{j}\right)\right. \\
& \begin{array}{r}
S_{j}+p_{j} \leq S_{i} \\
\text { or } \quad S_{i}+p_{i} \leq S_{j}
\end{array}  \tag{i,j}\\
& {[R] \equiv \min \left\{\sum_{j t} c_{j t} z_{j t}\right.} \\
& {[\mathrm{M}] \equiv \min \left\{\sum_{g \in G} c^{g} \lambda_{g}\right.} \\
& \sum_{t=0}^{T-p_{j}} z_{j t}=1 \quad \forall j \in J \\
& \sum_{g \in G} \sum_{t=0}^{T-p_{j}} z_{j t}^{g} \lambda_{g}=1 \quad \forall j \in J \\
& \sum_{g \in G} \lambda_{g}=1 \\
& \sum_{j \in J} z_{j t}-\sum_{j \in J} z_{j, t-p_{j}}=0 \quad \forall t \geq 1 \\
& \left.\lambda_{g} \in\{0,1\} \forall g \in G\right\} \\
& \left.z_{j t} \in\{0,1\} \quad \forall j, t\right\}
\end{align*}
$$

## Machine scheduling: column-and-row generation

1. Solve the restricted extended formulation $\left[\bar{R}_{L P}\right]$ (start from a feasible one) and update dual prices.
2. Solve the pricing subproblem (obtain a pseudo schedule)

3. Disaggregate the subproblem solution in arc variables $z$.

4. If some of these variables $z$ are not in [ $\left.\bar{R}_{L P}\right]$, add them to it along with the associated flow conservation constraints, then go to step 1.
5. Otherwise stop (the current solution of [ $\left.\bar{R}_{L P}\right]$ is optimal for $[R]$ ).

## Restricted reformulations

$$
\begin{aligned}
& Z=\left\{z^{s}\right\}_{s \in S}-\text { a set of integer solutions of } Q, \bar{S} \subset S \\
& \bar{z} \text { - restriction of } z \text { to the components of } \bigcup_{s \in \bar{S}} \operatorname{supp}\left(z^{S}\right) \\
& \bar{G}=G(\bar{S})=\left\{g \in G: x^{g}=T z^{s}, s \in \bar{S}\right\} \\
& \begin{aligned}
{\left[\bar{R}_{L P}\right] \equiv \min \left\{\begin{array}{rlr}
c \bar{T} \bar{z} & & {\left[\bar{M}_{L P}\right] \equiv \min \left\{\sum_{g \in \bar{G}} c x^{g} \lambda_{g}\right.} \\
A \bar{T} \bar{z} & \geq a \\
\bar{H} \bar{z} & \geq \bar{h} \\
\bar{z} & \left.\in \mathbb{R}_{+}^{\bar{e}}\right\} & \sum_{g \in \bar{G}} A x^{g} \lambda_{g} \geq a \\
& & \sum_{g \in \bar{G}} \lambda_{g}=1
\end{array} l\right.}
\end{aligned} \\
& \left.\lambda \in \mathbb{R}_{+}^{|\bar{G}|}\right\}
\end{aligned}
$$

Proposition

$$
v^{\left[M_{L P}\right]}=v^{\left[R_{L P}\right]} \leq v^{\left[\bar{R}_{L P}\right]} \leq v^{\left[\bar{M}_{L P}\right]}
$$

## Column-and-row generation procedure

Step 0: Initialize the dual bound, $\beta:=-\infty$, and a subset $\bar{S}$ so that $\left[\bar{R}_{L P}\right]$ is feasible.
Step 1: Solve $\left[\bar{R}_{L P}\right]$ and collect its dual solution $\bar{\pi}$ associated to constraints $A \bar{T} \bar{z} \geq a$.
Step 2: Obtain a solution $z^{*}$ of the pricing problem:

$$
\min \{(c-\bar{\pi} A) T z: z \in Z\}=\min \{(c-\bar{\pi} A) x: x \in X\}
$$

Step 3: Compute the Lagrangian dual bound: $L(\bar{\pi}) \leftarrow \bar{\pi} a+(c-\bar{\pi} A) T z^{*}$, and update
$\beta \leftarrow \max \{\beta, L(\bar{\pi})\}$. If $v^{\left[\bar{R}_{L P}\right]} \leq \beta$, STOP.
Step 4: Update the current bundle $\bar{S}$ by adding solution $z^{*}$ and update $\left[\bar{R}_{L P}\right]$. Go to Step 1.

## Proposition

Either $v^{\left[\bar{R}_{L P}\right]} \leq \beta$ (stopping condition), or some of the components of $z^{*}$ have negative reduced cost in $\left[\bar{R}_{L P}\right]$.

## Example: multi-item multi-echelon lot sizing

$y_{e t}^{k}$ - setup for item $k$ at echelon $e$ in period $t$
$x_{e t}^{k}$ - production for item $k$ at echelon $e$ in period $t$

$$
\begin{aligned}
{[F] \equiv \min \{ } & \sum_{k e t}\left(c_{e t}^{k} x_{e t}^{k}+f_{e t}^{k} y_{e t t}^{k}\right): \\
& \sum_{k} y_{e t}^{k} \leq 1 \quad \forall e, t \\
& \sum_{\tau=1}^{t} x_{e \tau}^{k} \geq \sum_{\tau=1}^{t} x_{e+1, \tau}^{k} \quad \forall k, e<E, t \\
& \sum_{\tau=1}^{t} x_{E \tau}^{k} \geq D_{1 t}^{k} \quad \forall k, t \\
& x_{e t}^{k} \leq D_{t T}^{k} y_{e t}^{k} \quad \forall k, e, t \\
& x_{e t}^{k} \geq 0 \quad \forall k, e, t \\
& \left.y_{e t}^{k} \in\{0,1\} \quad \forall k, e, t\right\}
\end{aligned}
$$

## Multi-echelon lot sizing: extended formulation

Dominance property
There exists an optimal solution in which $x_{e t} \cdot s_{e t}=0 \forall k, e, t \Rightarrow$ production plan for every item $k$ is a directed tree:

Dynamic programming
State ( $e, t, a, b$ ) corresponds to accumulating at echelon $e$ in period $t$ a production covering exactly the demand of periods $a, \ldots, b$. Extended formulation follows from [Martin et al].

## A generalization

Relaxed assumption
There exists a polyhedron

$$
Q=\left\{H z \geq h, z \in \mathbb{R}_{+}^{e}\right\}
$$

and transformation $T$ s.t. $Q$ defines a tighter formulation for $X$ :

$$
\operatorname{conv}(X) \subset \operatorname{proj}_{x} Q=\left\{x=T z: H z \geq h, z \in \mathbb{R}_{+}^{e}\right\} \subset P
$$

Consequences

- Column-and-row procedure is still valid
- However, in general, the dual bound is not as tight as $v^{\left[M_{\llcorner\rho]}\right]}$.

## Contents

## Motivation

Methodology

Interest of the approach

## Numerical results and conclusions

## Column-and-row generation vs. column generation

Proposition reminder

$$
v^{\left[M_{L P}\right]}=v^{\left[R_{L P}\right]} \leq v^{\left.\overline{\bar{R}}_{L P}\right]} \leq v^{\left[\bar{M}_{L P}\right]} .
$$

Remark
Column-and-row generation can converge faster than the standard column generation.
But when (and why) this happens?

Recombination property
Given $\bar{S}$, subproblem solutions $z^{1}, \ldots, z^{k} \in Z(\bar{S})$ can be recombined in a new solution $\hat{z} \in\left[\bar{R}_{L P}\right]$ such that $\hat{z} \notin \operatorname{conv}(Z(\bar{S}))$.

Machine scheduling: recombination property

$$
z(\bar{S})=\left\{z^{1}, z^{2}\right\}, \quad \hat{z} \in\left[\bar{R}_{L P}\right]
$$

## Machine Scheduling: results with smoothing

Both column and column-and-row generation are stabilized with smoothing: pricing problem is solved for the vector of dual values which is a linear combination of current dual solution and the stability center (smoothing parameter $\alpha$ is the best possible).

|  |  | Colomn gen. |  | Column-and-row gen. |  |  |

| 5 | 20 | 100 | 362 | 4657.8 | 56 | $0.01 \%$ | 386.1 |

## Conclusions

1. Column generation for an extended formulation is to be considered when:

- The extended formulation is obtained using a decomposition.
- SP solutions can be recombined into alternative ones.

2. The approach can be interpreted as a stabilization method for column generation:

- disaggregation helps,
- related to the use of exchange vectors,
- combined effect with other stabilization techniques (e.g. smoothing).

3. Computational results (ours and in the literature) show that this can be a competitive approach.

## Bin Packing: results with smoothing

- Bin capacity is 4000
- Item sizes are generated uniformly in intervals [1000, 3000] ("a2"), [1000, 1500] ("a3"), and [800, 1300] ("a4")
- Averages for 5 instances are given
