Abstract

We consider a system of a nucleus with an electron together with the quantized electromagnetic field. Instead of fixing the nucleus, the system is confined by its center of mass. This model is used in theoretical physics to explain the Lamb-Dicke effect (see [CTDRG]). When an ultraviolet cut-off is imposed we initiate the spectral analysis of the Hamiltonian describing the system and we derive the existence of a ground state. This is achieved without condition on the fine structure constant.

1 Introduction and statements of results

In this paper we address the problem of the existence of a ground state for the hydrogen atom and more generally for the hydrogeno¨ıd ion confined by its center of mass. The fact that the nucleus is confined but not fixed is important since intense rays appearing in the scattering spectrum for dynamical nucleus disappear when the nucleus is fixed (see [CTDRG]). This model is used to explain the Lamb-Dicke effect (see [CTDRG]). Some questions related to this problem have been considered in [Fe].

We consider a system of one nucleus and one electron, together with the electromagnetic field. Here the nucleus is dynamical and our Hamiltonian acts on an Hilbert space describing the nucleus, the electron and the photons. The center of mass of the system is confined by an external potential. Let us denote by $U$ (resp. $V$) the external confining potential (resp. the attractive Coulomb potential). The Hamiltonian of the system is $H_U^V$ and $H_U^V(m)$ is the corresponding operator if we decide that the photons have a positive mass $m > 0$.

The main result is theorem 1.4 below giving the existence of a ground state for $H_U^V$. In order to establish it we follow the fundamental strategy of [GLL] and [LL] (see also [G]). However we only reproduce here the new aspects of the proofs and often refer to [GLL] and [LL]. Precisely our contributions are essentially the following three points which are not straightforward modifications of [GLL] and [LL], the first point being the main one.

- The proof of the binding condition (theorem 1.3(ii)) (see section 3.2).
- The systematic use of quadratic forms throughout the paper. In particular, with the help of [H1] and the functional integration method we determine $Q(H_U^V), Q(H_U^V(m))$. This allows us to get $Q(H_U^V(m)) = Q(H_U^V) \cap Q(N)$ where $N$ is the number operator for the photons (see section 2). This appears to be useful in order to obtain rigorous results. In particular, we always consider $q_{H_U^V}(\varphi, \phi), q_{H_U^V(m)}(\varphi, \phi), \ldots$ instead of $(\varphi, H_U^V(\phi), (\varphi, H_U^V(m)\phi), \ldots$
- The proof of the exponential decay for the ground state of $H_U^V(m)$ (without using [G]). To this end we introduce the localization functions $\phi_{1,T}, \phi_{2,T}, \phi_{3,T}$, then we follow the standard method (see section 4.2).

Remark 1.1 (i) The proof of the other binding condition (theorem 1.3(i)) is closer to theorem 2.1 of [GLL] and is given in section 3.1.

(ii) The existence of a ground state for $H_U^V(m)$ follows these two binding conditions and [GLL] when the localization functions (for the electrons and the nucleus) have been properly chosen (see section 4.1).

Let us state precisely our results (theorems 1.1-1.4 below). We first define $H_U^V$ precisely using quadratic forms:

**Theorem 1.1** $H_U^V$ defines a self-adjoint operator.

**Remark 1.2** The hypotheses on the confining potential $U$ are stated in section 2.
Theorem 1.2 Assume that \( E(H_{VU}) < \min(E(H^0_{V}), E(H^1_{V})) \). Then \( H_{VU} \) has a ground state.

The assumptions in theorem 1.2 are the so-called binding conditions.

Here we obtain the existence of the ground state without assuming any conditions on the smallness for the different charges. We follow the strategy of [G], [GLL] and [LL] where the authors consider a similar system (actually more general) but with \textit{fixed} nuclei and succeed to deal with the quantized electromagnetic field in a non perturbative way. The heart of the proof is to specify correctly the \textit{binding conditions}. These conditions need to be properly chosen so that, on one side we are able to prove them and on the other side they imply the existence of a ground state.

The main result of the paper is theorem 1.3(ii).

Theorem 1.3 The following inequalities are true.

\[
(i) \quad E(H_{VU}) < E(H^0_{V}) \quad , \quad (ii) \quad E(H_{VU}) < E(H^1_{U}).
\]

Theorem 1.2 and 1.3 imply

Theorem 1.4 \( H_{VU} \) has a ground state for all value of the fine structure constant.

The proof of the existence of the ground state once the binding conditions are assumed (theorem 1.2) and the proof of the first binding condition (theorem 1.3(i)) are derived in the same way as in [GLL]. Indeed, \( H^0_{V} \) is a translation invariant operator. The translation invariance is a key point in the proof of theorem 2.1 of [GLL]. The validity of the remaining binding condition (theorem 1.3(ii)) is more difficult because \( H^0_{U} \) is not translation invariant and its proof borrows ideas of [LL] and still uses tools given in [LL].

For the sake of simplicity the spin of the electron is not taken into account in this work. This and the case of several electrons should be treated in a similar manner.

As it is already mentioned intense rays should appear in the spectrum of \( H_{VU} \). This may provide resonances with a very small imaginary part among other resonances. The resonances for \( H_{VU} \) are studied in [F] following mainly [BFS1][BFS2].

These results have been announced in [AF]. Let us also mention another case of a similar system with a dynamical nucleus: the case of free atoms and ions with quantized electromagnetic field. It is analyzed in [AGG].

The paper is organized as follows. In section 2 we verify theorem 1.1. In section 3, theorem 1.3 is derived. Finally, we prove theorem 1.2 in section 4.

2 Definition of the Hamiltonian

2.1 Fock space, creation and annihilation operators

The Hilbert space in which operate the Hamiltonian considered in this paper is

\[
\mathcal{H} := L^2(\mathbb{R}^6) \otimes \mathcal{F}_s \simeq L^2(\mathbb{R}^6; \mathcal{F}_s),
\]
where \( L^2(\mathbb{R}^6) \simeq L^2(\mathbb{R}^3) \otimes L^2(\mathbb{R}^3) \) is the space of states describing the nucleus together with the electron, and where \( \mathcal{F}_s \) is the bosonic Fock space over \( L^2(\mathbb{R}^3; \mathbb{C}^2) \). This Fock space describes the states of the polarized radiation field and is defined by

\[
\mathcal{F}_s = \mathcal{F}_s(L^2(\mathbb{R}^3)) \otimes \mathcal{F}_s(L^2(\mathbb{R}^3)),
\]

where \( \mathcal{F}_s(L^2(\mathbb{R}^3)) = \mathbb{C} \oplus \bigoplus_{n \geq 1} S_n L^2(\mathbb{R}^{3n}; \mathbb{C}) \), and where \( S_n L^2(\mathbb{R}^{3n}; \mathbb{C}) \) is the set of all elements \((k_1, \ldots, k_n) \mapsto \Phi(k_1, \ldots, k_n) \in L^2(\mathbb{R}^{3n}; \mathbb{C})\) which are invariant under any permutations of \( \{k_1, \ldots, k_n\} \). Note that

\[
\mathcal{F}_s \simeq \mathbb{C} \oplus \bigoplus_{n \geq 1} S_n \otimes_{\mathbb{C}} L^2(\mathbb{R}^3; \mathbb{C}^2).
\]

Moreover \( \mathcal{F}_s(L^2(\mathbb{R}^3)) \) (respectively \( \mathcal{F}_s^0(L^2(\mathbb{R}^3)) \)) is defined as the set of all \( \Phi = (\Phi^{(0)}, \Phi^{(1)}, \Phi^{(2)}, \ldots) \) in \( \mathcal{F}_s(L^2(\mathbb{R}^3)) \) (respectively in \( \mathcal{F}_s \)) such that \( \Phi^{(n)} = 0 \) except for a finite number of terms.

For any \( f \in L^2(\mathbb{R}^3) \), the creation operator \( a^*(f) \) and the annihilation operator \( a(f) \) are defined for all \( \Phi \in \mathcal{F}_s(L^2(\mathbb{R}^3)) \) by

\[
\begin{align*}
(a^*(f)\Phi)^{(n)}(k_1, \ldots, k_n) &:= \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \hat{f}(k_j) \Phi^{(n-1)}(k_1, \ldots, \hat{k}_j, \ldots, k_n), \\
(a(f)\Phi)^{(n)}(k_1, \ldots, k_n) &:= \frac{1}{\sqrt{n+1}} \int_{\mathbb{R}^3} \frac{\hat{f}(k) \Phi^{(n+1)}(k, k_1, \ldots, k_n) dk}{},
\end{align*}
\]

where \( \hat{k}_j \) means that the variable \( k_j \) is missing in \( \Phi^{(n-1)} \), and where \( \hat{f} \) is the Fourier transform of \( f \). These operators are closable on \( \mathcal{F}_s(L^2(\mathbb{R}^3)) \) (their closed extensions are denoted by the same symbols) and they verify on \( \mathcal{F}_s(L^2(\mathbb{R}^3)) \)

\[
[a(f), a^*(g)] = (f, g), \quad [a(f), a(g)] = [a^*(f), a^*(g)] = 0, \quad (a(f) \Phi, \Psi) = (\Phi, a^*(f)\Psi).
\]

Let

\[
D_S := \left\{ \Phi \in \mathcal{F}_s(L^2(\mathbb{R}^3)), \Phi^{(n)} \in S(\mathbb{R}^{3n}) \text{ for all } n \right\},
\]

where \( S(\mathbb{R}^{3n}) \) denotes the Schwartz space over \( \mathbb{R}^{3n} \), and let

\[
\begin{align*}
(\hat{a}(k)\Phi)^{(n)}(k_1, \ldots, k_n) &:= \frac{1}{\sqrt{n+1}} \Phi^{(n+1)}(k, k_1, \ldots, k_n), \\
(\hat{a}^*(k)\Phi)^{(n)}(k_1, \ldots, k_n) &:= \frac{1}{\sqrt{n}} \sum_{l=1}^{n} \delta(k-k_l) \Phi^{(n-1)}(k_1, \ldots, \hat{k}_l, \ldots, k_n)
\end{align*}
\]

as quadratic forms on \( D_S \times D_S \).

Then in the sense of quadratic forms on \( D_S \times D_S \) we have:

\[
a^*(f) = \int_{\mathbb{R}^3} \hat{a}^*(k) \hat{f}(k) dk, \quad a(f) = \int_{\mathbb{R}^3} \hat{a}(k) f(k) dk.
\]

Now for \( \lambda = 1, 2 \) and \( f \in L^2(\mathbb{R}^3) \), \( a^\#(f) \) are defined to be the closures in \( \mathcal{F}_s \) of

\[
a^\#_\lambda(f) = a^\#(f) \otimes I, \quad a^\#_\lambda(f) = I \otimes a^\#(f),
\]

\[
[1, \ldots, k_n \mapsto \Phi(k_1, \ldots, k_n) \in L^2(\mathbb{R}^{3n}; \mathbb{C})] \]
where \( a^\# \) stands for \( a \) or \( a^* \).

\( \hat{a}^\#(k) \) is defined as a quadratic form on \((D_S \otimes D_S)^2\) similarly.

It follows that on \( F_s^0 \)

\[
[a_\lambda(f), a_\lambda^*(g)] = \delta_{\lambda\lambda'}(f, g), \quad [a_\lambda(f), a_\lambda^*(g)] = [a_\lambda^*(f), a_\lambda^*(g)] = 0.
\]

If \( f \in L^2(\mathbb{R}^3; \mathbb{C}^2) \), we can write \( f = (f_1, f_2) \) with \( f_1 \) and \( f_2 \) in \( L^2(\mathbb{R}^3) \), and \( a^\#(f) \) is defined by

\[
a^\#(f) = \sum_{\lambda=1,2} a_\lambda^\#(f_\lambda).
\]

Finally, for \( \lambda = 1, 2 \), define the creation and annihilation operators acting in the configuration space by

\[
a_\lambda^*(y) := \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} \hat{a}_\lambda^*(k)e^{-ik\cdot y}dk, \quad a_\lambda(y) := \frac{1}{(2\pi)^{3/2}} \int_{\mathbb{R}^3} \hat{a}_\lambda(k)e^{ik\cdot y}dk,
\]

as quadratic forms on \((D_S \otimes D_S)^2\). Then we have

\[
a^*(f) = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} a_\lambda^*(y)f_\lambda(y)dy, \quad a(f) = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} a_\lambda(y)f_\lambda(y)dy,
\]

in the sense of quadratic forms.

The number operator \( \mathcal{N} \) is defined by

\[
(\mathcal{N}\Phi)^{(n)}(k_1, \ldots, k_n) = n\Phi(k_1, \ldots, k_n)
\]

for all \( \Phi \in D(\mathcal{N}) = \left\{ \Phi \in F_s, \sum_{n \geq 1} n\|\Phi^{(n)}\|_{\mathbb{C}^{\otimes n}}^2 < \infty \right\} \), and it is easy to see that \( \mathcal{N} \) is self-adjoint on \( D(\mathcal{N}) \). In the sense of quadratic forms, \( \mathcal{N} \) is given by

\[
\mathcal{N} = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \hat{a}_\lambda^*(k)\hat{a}_\lambda(k)dk.
\]

Moreover \( D(\mathcal{N}^{1/2}) = \left\{ \Phi \in F_s, \sum_{n \geq 1} n^{1/2}\|\Phi^{(n)}\|_{\mathbb{C}^{\otimes n}} < \infty \right\} \) and we have

\[
(\mathcal{N}^{1/2}\Phi)^{(n)}(k_1, \ldots, k_n) = n^{1/2}\Phi(k_1, \ldots, k_n)
\]

for all \( \Phi \in D(\mathcal{N}^{1/2}) \).

As in [LL] we can decompose an element of \( F_s \) in a suitable basis. Namely if \( (f_i)_{i \in \mathbb{N}} \) is an orthonormal basis of \( L^2(\mathbb{R}^3; \mathbb{C}^2) \), the vectors of the form

\[
|i_1, p_1; \ldots; i_n, p_n\rangle_f := \frac{1}{\sqrt{p_1! \cdots p_n!}} a^*(f_{i_1})^{p_1} \cdots a^*(f_{i_n})^{p_n}\Omega
\]

constitute an orthonormal basis of \( F(L^2(\mathbb{R}^3; \mathbb{C}^2)) \) (where \( \Omega = (1, 0, 0, \ldots) \) denotes the vacuum vector in Fock space). Any \( \Phi \in F_s \) can be written as

\[
\Phi = \sum_{n \geq 0} \sum_{i_1 < i_2 < \cdots < i_n} \sum_{p_1, \ldots, p_n} \Phi_{i_1, p_1; \ldots; i_n, p_n} |i_1, p_1; \ldots; i_n, p_n\rangle_f,
\]

where the term for \( n = 0 \) in the sum is a constant times \( \Omega \).
2.2 Definition of the Hamiltonian

We denote by $m_1$ and $q_1$ the mass and the charge of the electron respectively, and by $m_2$ and $q_2$ the mass and the charge of the nucleus. Moreover $x_1$ and $p_1 := -i\hbar \nabla_{x_1}$ denote the position and the momentum of the electron, and $x_2$, $p_2$ are the position and the momentum of the nucleus.

Let

$$M = m_1 + m_2, \quad \mu = \frac{m_1 m_2}{m_1 + m_2}. \quad (17)$$

Then the variables $R, P$ of the center of mass, and the relative variables $r, p$ are defined by

$$R = \frac{m_1 x_1 + m_2 x_2}{M}, \quad P = p_1 + p_2, \quad r = x_1 - x_2, \quad p = \frac{p_1}{m_1} - \frac{p_2}{m_2}. \quad (18)$$

We assume that $\hbar = 1$ and $c = 1$ where $c$ is the velocity of light. Thus the Pauli-Fierz Hamiltonian of the system we consider is given as an operator acting in $\mathcal{H}$ by

$$H^Y := \sum_{j=1,2} \frac{1}{2m_j} (p_j - q_j A_j)^2 + H_f + V(r) + U(R). \quad (19)$$

Here $A_j := (A_j^1, A_j^2, A_j^3)$ is the quantized electromagnetic vector potential in the Coulomb gauge defined for $i = 1, 2, 3$ by

$$A_j^i = \int_{\mathbb{R}^3} A^i(x_j) dX, \quad (20)$$

where $X = (x_1, x_2)$ and for $x \in \mathbb{R}^3$

$$A^i(x) = a^*(h^i(x - \cdot)) + a(h^i(x - \cdot)), \quad (21)$$

where the coupling function $h^i = (h_1^i, h_2^i)$ is defined for $\lambda = 1, 2$ by

$$h_\lambda^i(y) = \frac{1}{2\pi} \int_{\mathbb{R}^3} \hat{\chi}_\Lambda(k) \frac{\sqrt{|k|}}{|k|} \epsilon_\lambda(k) e^{-ik.y} dk. \quad (22)$$

The vectors $\epsilon_\lambda$ used in the last definiton are the orthonormal polarization vectors in the Coulomb gauge. They are chosen as

$$\epsilon_1(k) = \frac{(k_2, -k_1, 0)}{\sqrt{k_1^2 + k_2^2}}, \quad \epsilon_2(k) = \frac{k}{|k|} \wedge \epsilon_1(k). \quad (23)$$

Note that $\epsilon_1(k)$ and $\epsilon_2(k)$ are well-defined and smooth only on $\mathbb{R}^3 \setminus Oz$ where $Oz$ is the axis $\{0, 0, k_3\}, k_3 \in \mathbb{R}$. But this singularity is not a problem in this paper.

Finally, $\Lambda$ is the parameter of the ultraviolet cutoff, and $\hat{\chi}_\Lambda$ is a real smooth function depending only on $|k|$, which is equal to 1 in the ball $B(0, \Lambda/2)$ and which vanishes outside the ball $B(0, \Lambda)$. It is well known that $A^i(x)$ is essentially self-adjoint on $\mathcal{F}^0_r$ for all $x \in \mathbb{R}^3$ (see [RS2]), and one can verify that in the sense of quadratic forms acting in the moment space

$$A(x) = \frac{1}{2\pi} \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \hat{\chi}_\Lambda(k) \frac{\sqrt{|k|}}{|k|} \epsilon_\lambda(k) \left( \tilde{a}_\lambda^*(k) e^{-ik.x} + \tilde{a}_\lambda(k) e^{ik.x} \right) dk. \quad (24)$$
The free energy field of the photons, \( H_f \), acts in \( \mathcal{F}_\alpha = \mathcal{F}_\alpha(L^2(\mathbb{R}^3)) \otimes \mathcal{F}_\alpha(L^2(\mathbb{R}^3)) \) and is defined by
\[
H_f := d\Gamma(\omega(-i\nabla)) \otimes I + I \otimes d\Gamma(\omega(-i\nabla)),
\] (25)
where \( w(k) = |k| \), and where \( d\Gamma(A) \) denotes the second quantization of the self-adjoint operator \( A \). The massive photon field \( H_f(m) \) will be defined by replacing \( \omega(k) = |k| \) with \( \omega_m(k) = \sqrt{k^2 + m^2} \), \( m > 0 \), in the definition of \( H_f \). Then the massive Hamiltonian \( H_V^m \) is \( H_V^m \) with \( H_f(m) \) replaced by \( H_f \).

\( H_f \) is essentially self-adjoint on \( D_S \otimes D_S \) and we have
\[
H_f = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} |k| \hat{a}_\lambda^*(k) \hat{a}_\lambda(k) dk
\] (26)
as a quadratic form acting in the moment space.

\( V \) is the attractive Coulomb potential and is defined by
\[
V(r) = -\frac{C}{|r|},
\] (27)
where \( C \) is a positive constant.

Finally, \( U \) is a confining potential for which we make the following assumptions:
\[
(H_0) \left\{ \begin{array}{l}
\text{(i)} \ U \in L^1_{\text{loc}}(\mathbb{R}^3), \\
\text{(ii)} \ \inf(U(R)) > -\infty \text{ and } U^- \text{ is compactly supported}, \\
\text{(iii)} \ P^2/2M + U \text{ has a non-degenerate ground state } \phi > 0 \text{ with energy } -e_0 < 0,
\end{array} \right.
\]
and there exists \( \gamma \) such that \( |\phi(R)| \leq \gamma e^{-|R|/\gamma} \).

In the next subsection we precise the relations between domains of self-adjointness (or domains of quadratic forms) for the operators that we work with in this paper.

### 2.3 Self-adjointness and quadratic forms domains

Let \( q \) be the quadratic form defined by
\[
q(\Phi, \Psi) := \sum_{j=1,2} \frac{1}{2m_j} ((p_j - q_j A_j)\Phi, (p_j - q_j A_j)\Psi) + (H_f^{1/2}\Phi, H_f^{1/2}\Psi).
\] (28)

**Lemma 2.1** \( q \) is closed on \( Q(p_1^2 + p_2^2) \cap Q(H_f) \).

**Proof** First we have to verify that \( q \) is well-defined on \( Q(p_1^2 + p_2^2) \cap Q(H_f) \). Lemma A.4 of [GLL] shows that
\[
(A_j \Phi, A_j \Phi) \leq 32\pi \Lambda \left[ (H_f^{1/2}\Phi, H_f^{1/2}\Phi) + \frac{\Lambda}{8} (\Phi, \Phi) \right],
\] (29)
for all \( \Phi \in C_0^\infty(\mathbb{R}^6) \otimes D_S \).

Since \( C_0^\infty(\mathbb{R}^6) \otimes D_S \) is a core for \( H_f^{1/2} \), this proves that \( Q(H_f) \subset D(A_j) \). Hence \( q \) is well-defined.
Next let us show that \( q \) is closed on \( Q(p_1^2 + p_2^2) \cap Q(H_f) \). By lemma A.5 of [GLL], we have, for all \( \Phi \in Q(p_1^2 + p_2^2) \cap Q(H_f) \),

\[
(H_f^{1/2} \Phi, H_f^{1/2} \Phi) \leq q(\Phi, \Phi), \\
\sum_{j=1,2} \langle p_j \Phi, p_j \Phi \rangle \leq a q(\Phi, \Phi) + b(\Phi, \Phi),
\]

where \( a, b \) are positive real numbers.

If \( \Phi_n \in Q(p_1^2 + p_2^2) \cap Q(H_f) \) is such that \( \Phi_n \to \Phi \) and \( q(\Phi_n - \Phi_m, \Phi_n - \Phi_m) \to 0 \), then (30) yields \( \Phi \in Q(H_f) \) and (31) yields \( \Phi \in Q(p_1^2) \cap Q(p_2^2) \). Hence \( q \) is closed. \( \square \)

In addition, we see that \( q \) is positive. Thus, there exists a unique self-adjoint operator, that we call \( H_0^U \), associated with \( q \). In other words, \( q = q_{H_U} \) (where \( q_A \) denotes the quadratic form associated with the self-adjoint operator \( A \)).

**Lemma 2.2** \( V - U^- \) is relatively bounded with respect to \( q \) in the sense of forms, with relative bound 0.

**Proof** According to the assumption \((H_0)\), \( U^- \) is infinitesimally small with respect to \( P^2 \). Moreover the Coulomb potential \( V \) is infinitesimally small with respect to \( p^2 \). Thus, \( V - U^- \) is infinitesimally small with respect to \( p_1^2 + p_2^2 \) since we have

\[
\frac{p_1^2}{2m_1} + \frac{p_2^2}{2m_2} = \frac{P^2}{2M} + \frac{p^2}{2\mu}.
\]

Then \( V - U^- \) is infinitesimally form-bounded with respect to \( p_1^2 + p_2^2 \) (see [RS2, theorem X.18]). We conclude with (31). \( \square \)

With the help of this lemma and the KLMN theorem, we define \( H_U^V \) as the self-adjoint operator associated with the closed and semi-bounded quadratic form \( q_{H_U^V, -} \) defined on \( Q(p_1^2 + p_2^2) \cap Q(H_f) \) by \( q_{H_U^V, -} = q + q_{V - U^-} \). Next, we define the Hamiltonian \( H_U^V \) by

\[
H_U^V := H_U^{V, -} + U^+,
\]

that is to say, \( H_U^V \) is the self-adjoint operator associated with the closed and semi-bounded quadratic form \( q_{H_U^V} \) defined on \( Q(H_U^{V, -}) \cap Q(U^+) \) by \( q_{H_U^V} = q_{H_U^{V, -}} + q_{U^+} \).

**Remark 2.1** One could have defined the Hamiltonian of the system using a Schrödinger representation of \( \mathcal{F}_s \), say \( L^2(Q, d\mu) \). Namely, it is proved in [H1] that the operator \( \tilde{H}_0 \) defined on \( D(p_1^2 + p_2^2) \cap D(H_f) \) by

\[
\tilde{H}_0 := \sum_{j=1,2} \frac{1}{2m_j} (p_j - q_j A_j)^2 + H_f
\]

is self-adjoint. This result is obtained thanks to FKN and FKI formulae that lead to the following functional integral representation:

\[
(F, e^{-t\tilde{H}_0} G) = \int_{M} (F(X_0), J_1(X)G(X_1))_{L^2(Q)} \, dX.
\]
Here, $M = \mathbb{R}^6 \times P$, where $(P, db)$ is a probability measure space associated with the 6-dimensional Brownian motion \( \{b(t)\}_{t\geq 0} \), and $X_t = X + b(t)$ is the Wiener process on $M$.

Moreover,
\[
J_t(X) = \Xi_t^* e^{-i\phi_0(K(t))} \Xi_t,
\]
where $\Xi_t$ is the second quantization of $\oplus^3 \xi_t$. The isometry $\xi_t : \oplus^3 L^2(\mathbb{R}^3) \rightarrow \oplus^3 L^2(\mathbb{R}^4)$ is defined by
\[
\hat{\xi}_t f(k,k_0) = \frac{e^{-ik_0}}{\sqrt{\pi}} \sqrt{\frac{\omega(k)}{\omega(k)^2 + |k_0|^2}} \hat{f}(k).
\]

$\phi_0(f)$ is a Gaussian random process indexed by real $f \in \oplus^3 L^2(\mathbb{R}^4)$, on a probability measure space $(Q_0, d\mu_0)$. Finally, $K(t)$ is the stochastic integral
\[
K(t) = \oplus_{i=1}^3 q_1 \int_0^t \xi_s \rho(\cdot - X_s) db_s^1(s) + \oplus_{i=1}^3 q_2 \int_0^t \xi_s \rho(\cdot - X_s) db_s^2(s),
\]
with $\hat{\rho}(k) = \hat{\chi}_\Lambda(k)/\left(\pi \sqrt{2|m|}\right)$.

Next it is proved that $V - U^-$ is infinitesimally small with respect to $\hat{H}_0$, so that the Kato-Rellich theorem gives a meaning to $\hat{H}^Y_U := \hat{H}_0 + V - U^-$.

Finally, $\hat{H}^Y_U$ is defined in the same way as for $H^Y_U$, that is $\hat{H}^Y_U := \hat{H}^Y_U - U^+$.

Let us show here that the two definitions of the Hamiltonian are the same:

**Proposition 2.1** $H^Y_U = \hat{H}^Y_U$.

**Proof** This will follow from two lemmata:

**Lemma 2.3** Let $A$ be a semi-bounded self-adjoint operator and let $B$ be a self-adjoint operator that is relatively bounded with respect to $A$ with a relative bound strictly less than 1. Then
\[
A + B = A + B,
\]
that is to say the definitions given by the Kato-Rellich theorem and the KLMN theorem respectively lead to the same operator.

**Proof** We easily see that $q_{A+B}$ equals $q_{A+B}$ on $D(A)$, and since this domain is a form core for each of the two closed quadratic forms, we get $q_{A+B} = q_{A+B}$. Moreover, since $A$ is semi-bounded, we can see that the two quadratic forms are semi-bounded. This yields $A + B = A + B$. \(\square\)

**Lemma 2.4** $H^0_U = \hat{H}_0$.

**Proof** Since $q_{H^0_U}$ and $q_{\hat{H}^0_U}$ are positive, it is sufficient to show that these two closed quadratic forms are equal on a domain that is a form core for the two of them. According to [H1], $C^\infty(\mathbb{R}^6) \otimes D_S$ is a core for $\hat{H}_0$. Thus it is a form core for $q_{\hat{H}_0}$. Let us show that it is also a form core for $q_{H^0_U}$.

By lemma A.4 of [GLL], we have
\[
q_{H^0_U}(\Phi, \Phi) \leq \sum_{j=1,2} \frac{1}{2m_j} \left[ (1 + |q_j|) (\rho \Phi, \rho \Phi) + (|q_j| + q_j^2)(32\pi \Lambda (H^{1/2}_j \Phi, H^{1/2}_j \Phi) + 4\pi \Lambda^2 (\Phi, \Phi)) \right] + (H^{1/2}_j \Phi, H^{1/2}_j \Phi).
\]
We note that the inequalities $|H| \leq C \in [GLL]$ that $E$ to see that $Q$.

Thus we sketch the proof (see [GLL, theorem 5.1] for more details). Namely, if $\Phi_n \to 0$. We will denote by $q_{H_U}^\infty(\Phi,\Phi) \to 0$. Hence $C_0^\infty(\mathbb{R}^6) \otimes D_S$ is a form core for $q_{H_U}$.

Now, $H_U^0(m)$ is defined similarly by $H_U^0(m) := H_U^0(m) + U^+$, so that we have

$$Q(H_U^0(m)) = Q(p_U^2 + p_V^2) \cap Q(H_f(m)) \cap Q(U^+).$$

We note that the inequalities $|k| \leq \sqrt{k^2 + m^2} \leq |k| + m$, for all $k \in \mathbb{R}^3$, yield

$$Q(H_f(m)) = Q(H_f) \cap Q(N), \quad Q(H_U^0(m)) = Q(H_U^0) \cap Q(N).$$

### 2.4 Massive and massless ground state energy

In this subsection we recall (see [GLL, part. 5]) that the ground state energy of the massive Hamiltonian $H_U^0(m)$, $m > 0$, converges to the ground state energy of the massless one as $m$ goes to 0. We will denote by $E(A)$ the infimum of the spectrum of any semi-bounded self-adjoint operator $A$, so that we have

$$E(A) = \inf_{\phi \in D(A), \|\phi\|=1} (\phi, A\phi) = \inf_{\phi \in Q(A), \|\phi\|=1} q_A(\phi, \phi).$$

**Lemma 2.5** $E(H_U^0(m)) \to E(H_U^0)$.

**Proof** We sketch the proof (see [GLL, theorem 5.1] for more details). Namely, if $m > m' > 0$, we have $Q(H_U^0(m)) = Q(H_U^0(m')) \subset Q(H_U^0)$ by (40). Then

$$E(H_U^0) = \inf_{\|\Psi\|=1, \Psi \in Q(H_U^0)} q_{H_U^0}(\Psi, \Psi) = \inf_{\|\Psi\|=1, \Psi \in Q(H_U^0(m))} q_{H_U^0}(\Psi, \Psi) \leq \inf_{\|\Psi\|=1, \Psi \in Q(H_U^0(m'))} q_{H_U^0}(\Psi, \Psi) = E(H_U^0(m')) \leq \cdots \leq E(H_U^0(m)).$$

Thus $E(H_U^0(m))$ converges to a limit $E^*$ that is greater than $E(H_U^0)$ when $m$ goes to 0.

To see that $E^* \leq E(H_U^0)$, let $\varepsilon > 0$ and take $\Psi_0 \in Q(H_U^0)$ such that $\|\Psi_0\| = 1$ and $q_{H_U^0}(\Psi_0, \Psi_0) \leq E(H_U^0) + \varepsilon$.

If $\Pi_n$ denotes the projector onto $F(n) := \{ \Phi \in F, \Phi(k) = 0 \text{ for all } k > n \}$, then we can see as in [GLL] that $q_{H_U^0}(\Pi_n \Psi_0, \Pi_n \Psi_0) \to q_{H_U^0}(\Psi_0, \Psi_0)$. We set $\Psi_0 := \Pi_n \Psi_0$ where $n_0$ is chosen such that $\left| q_{H_U^0}(\Pi_{n_0} \Psi_0, \Pi_{n_0} \Psi_0)/\|\Pi_{n_0} \Psi_0\|^2 - q_{H_U^0}(\Psi_0, \Psi_0) \right| \leq \varepsilon$. Then we have

$$\Psi_0 \in Q(H_U^0) \cap Q(N) = Q(H_U^0(m))$$

for all $m > 0$, so that

$$E(H_U^0(m)) = \inf_{\Psi \in Q(H_U^0(m)), \|\Psi\|=1} q_{H_U^0(m)}(\Psi, \Psi) \leq q_{H_U^0(m)}(\Psi_0, \Psi_0)/\|\Psi_0\|^2$$

$$\leq q_{H_U^0}(\Psi_0, \Psi_0)/\|\Psi_0\|^2 + m.q(\Psi_0, \Psi_0)/\|\Psi_0\|^2$$

$$\leq q_{H_U^0}(\Psi_0, \Psi_0) + \varepsilon + m.n_0 \leq E(H_U^0) + 2\varepsilon + m.n_0.$$
Letting $m \to 0$, next $\varepsilon \to 0$, we get the stated result. 

Note that the same result holds when $H^V_U$ is replaced by $H^V_0$ (respectively $H^0_U$).

### 3 Binding conditions

As in [GLL], the key step is to define binding conditions under which we are able to prove that a ground state exists for the Hamiltonian $H^V_U$. We define the binding conditions as:

$$
E(H^V_U) < E(H^V_0),
$$

$$
E(H^V_U) < E(H^0_U).
$$

The proof of the condition (i) follows the one in [GLL, theorem 2.1], whereas the proof of (ii) is more difficult and needs the localization methods used in [LL].

**Remark 3.1** Note that as soon as (i) and (ii) are satisfied, lemma 2.5 yields

$$
\min [E(H^V_0(m)), E(H^V_U(m))] - E(H^V_U(m)) \geq C > 0,
$$

for any suitable constant $C$ and any $m$ small enough.

### 3.1 Proof of condition (i)

Following [GLL, theorem 2.1], we shall show that $E(H^V_U) \leq E(H^V_0) - \varepsilon_0$. The point is to find a normalized state $\Phi \in Q(H^V_U)$ such that $q_{H^V_U}(\Phi, \Phi) - \langle \Phi, \frac{1}{2}E(H^V_0) - \varepsilon_0 + \varepsilon \rangle \Phi \leq 0$ (where $\varepsilon > 0$ is fixed).

Let $\varepsilon > 0$ and let $F \in D(H^V_0), \|F\| = 1$ such that $(F,H^V_U F) < E(H^V_U) + \varepsilon$. Define the unitary operator $U_y$ for all $y \in \mathbb{R}^3$ by

$$
U_y = e^{i\varepsilon_y \cdot (p_1 + p_2 + dT(-i\nabla))}.
$$

(42)

$U_y$ acts in $\mathcal{H}$, and if $\Psi \in \mathcal{H}$, $\Psi := \psi_{el} \otimes \alpha^*(f_1)^{\alpha_1} \cdots \alpha^*(f_n)^{\alpha_n} \Omega$, then we have

$$
U_y \Psi = \psi_{el}(\cdot + y, \cdot + y) \otimes \alpha^*(f_1(\cdot + y))^{\alpha_1} \cdots \alpha^*(f_n(\cdot + y))^{\alpha_n} \Omega.
$$

(43)

Since $[H^V_0, U_y] = 0$ on $C_0^\infty(\mathbb{R}^3) \otimes D_S$ and since this domain is a core for $H^V_0$ (see [H1]), then, for all $\Psi \in D(H^V_0)$, $U_y \Psi \in D(H^V_0)$ and $[H^V_0, U_y] \Psi = 0$.

Let us note here that, in particular, this translation invariance of $H^V_0$ is due to the fact that $V$ itself is translation invariant. But this becomes false if $V$ is replaced by $U$, so that we will have to face a difficulty through the proof of condition (ii).

Now, as in [GLL], we would like to choose $\Phi_y := \phi U_y F$, for a suitable $y$, as a trial state. First we have to show that $\Phi_y \in Q(H^V_U)$. We know that $\exists \gamma > 0$ such that $\phi(R) \leq \gamma e^{-|R|/\gamma}$ for all $R \in \mathbb{R}^3$. Thus, $\Phi_y \in \mathcal{H}$ for all $y$. Let $\xi_n(R) = \xi(R/n)$ be a smooth function in $C_0^\infty(\mathbb{R}^3)$ with $0 \leq \xi \leq 1$, $\xi = 1$ in the ball $B(0,1)$ and $\xi = 0$ outside the ball $B(0,2)$; let $\phi_n := \xi_n \phi$. Then $\Phi^\alpha := \phi_n U_y F \rightharpoonup \Phi_y$ in $\mathcal{H}$, and $\Phi^\alpha \in Q(H^V_U)$ since $\phi_n$ is a smooth, compactly supported...
function. Thus, to be able to conclude that $\Phi_y \in Q(H^Y_U)$, we only need to show that $q_{H^Y_U} (\Phi^n_y, \Phi^n_y)$ is bounded uniformly in $n$. Since $q_{H^Y_U}$ is semi-bounded from below, we would like to check that $q_{H^Y_U} (\Phi^n_y, \Phi^n_y)$ is bounded from above. But

$$q_{H^Y_U} (\Phi^n_y, \Phi^n_y) = \sum_{j=1,2} \frac{1}{2m_j} ((p_j - q_jA_j) \Phi^n_y, (p_j - q_jA_j) \Phi^n_y) + (\Phi^n_y, U \Phi^n_y) + (\Phi^n_y, [H_f + V] \Phi^n_y).$$

The last term of this sum is uniformly bounded from above since $V$ is negative, since $\phi^2(R) \leq \gamma e^{-|R|/\gamma}$ and since $(U_y F, H_f U_y F) < \infty$ (because $U_y F \in D(H^Y_U)$). As for the other terms, following [GLL], we can show

$$\sum_{j=1,2} \frac{1}{2m_j} ((p_j - q_jA_j) \Phi^n_y, (p_j - q_jA_j) \Phi^n_y) + (\Phi^n_y, U \Phi^n_y)

= \int_{\mathbb{R}^n} \phi_n(R) \left( \frac{P^2}{2M} + U \right) \phi_n(R) \langle U_y F(X), U_y F(X) \rangle dX

+ \sum_{j=1,2} \frac{1}{2m_j} \int_{\mathbb{R}^n} \phi_n(R)^2 ((p_j - q_jA(x_j))U_y F(X), (p_j - q_jA(x_j))U_y F(X)) dX

= -\epsilon_0 \int_{\mathbb{R}^n} \phi_n(R)^2 (U_y F(X), U_y F(X)) dX + \frac{1}{2M} \int_{\mathbb{R}^n} (P^2 \xi_n(R)) \xi_n(R) \phi(R)^2 (U_y F(X), U_y F(X)) dX

- \frac{1}{M} \int_{\mathbb{R}^n} \phi(R)^2 P[\xi_n(R)](P\xi_n(R)) (U_y F(X), U_y F(X)) dX

+ \sum_{j=1,2} \frac{1}{2m_j} \int_{\mathbb{R}^n} \phi_n(R)^2 ((p_j - q_jA(x_j))U_y F(X), (p_j - q_jA(x_j))U_y F(X)) dX.

All of the terms in this last sum are bounded from above, which can be seen using again the fact that $\phi(R) \leq \gamma e^{-|R|/\gamma}$ together with $\xi_n(R), (P\xi_n(R), (P^2 \xi_n(R)$ are uniformly bounded, and $U_y F \in D(H^Y_U)$. Therefore $\Phi_y \in Q(H^Y_U)$ for all $y \in \mathbb{R}^3$. In addition, we have

$$q_{H^Y_U} (\Phi_y, \Phi_y) = -\epsilon_0 \int_{\mathbb{R}^n} \phi(R) \langle U_y F(X), U_y F(X) \rangle dX + (\Phi_y, [H_f + V] \Phi_y)

+ \sum_{j=1,2} \frac{1}{2m_j} \int_{\mathbb{R}^n} \phi(R)^2 ((p_j - q_jA(x_j))U_y F(X), (p_j - q_jA(x_j))U_y F(X)) dX.

The end of the proof is the same as the one in [GLL]. That is we integrate $q_{H^Y_U} (\Phi_y, \Phi_y)$ in $y$ over $\mathbb{R}^3$ and do the changes of variables $x_1 + y \rightarrow x_1, x_2 + y \rightarrow x_2$, which leads to

$$\int_{\mathbb{R}^3} q_{H^Y_U} (\Phi_y, \Phi_y) dy = \int_{\mathbb{R}^3} (\Phi(u)^2 du \|[F, H^Y_U F] - \epsilon_0 (F, F)\|) = (F, H^Y_U F) - \epsilon_0,$$

since $\|\phi\|^{L_2(\mathbb{R}^3)} = 1$ and $\|F\|_M = 1$.

But we assumed $(F, H^Y_U F) < E(H^Y_U) + \epsilon$ and we have $\|\Phi_y\| = \|\phi\|\|F\| = 1$ so that

$$\int_{\mathbb{R}^3} q_{H^Y_U} (\Phi_y, \Phi_y) - [E(H^Y_U) - \epsilon_0 + \epsilon] (\Phi_y, \Phi_y) dy < 0.$$

Therefore $\exists y_0 \in \mathbb{R}^3$, and $\Phi_{y_0} \in Q(H^Y_U)$, which is necessary $\neq 0$, such that

$$q_{H^Y_U} (\Phi_{y_0}, \Phi_{y_0}) - [E(H^Y_U) - \epsilon_0 + \epsilon] (\Phi_{y_0}, \Phi_{y_0}) < 0.$$
Then \( E(H_V^U) < E(H_0^U) - \varepsilon_0 + \varepsilon \), and since this inequality is true for all \( \varepsilon > 0 \), we obtain
\[
E(H_V^U) \leq E(H_0^U) - \varepsilon_0.
\]

### 3.2 Proof of condition (ii)

As stated above, we can not follow the proof of the previous subsection because the Hamiltonian \( H_0^U \) is not translation invariant. Actually, if \( (F_j) \) denotes a minimizing sequence for \( H_0^U \) we can consider two possibilities: either a part of the support of \( F_j \) lies in a ball with fixed radius, or \( F_j \) is supported outside balls with increasing radius. In other words, consider a state “close to” the ground state. Then, the two particles of the system live either not too far from each other, or, on the contrary, as far as we want from each other. In the first case the proof is easy, whereas in the second case it is more difficult.

Namely, we shall localize the electronic particles together with the photons in a similar way as the one used in [LL]. This bring us to pay attention to a new Hamiltonian \( \tilde{H}_U^0 \) which operate in \( L^2(\mathbb{R}^6) \otimes \mathcal{F}_s \otimes \mathcal{F}_s \), and whose ground state energy is such that
\[
E(H_U^0) \geq E(\tilde{H}_U^0) > E(H_U^0),
\]
which will give the result.

We begin with the simplest case:

**Theorem 3.1** Let \( (F_j) \) be a normalized sequence in \( Q(H_0^U) \) such that \( q_{H_0^U}(F_j, F_j) \to \infty \) \( E(H_U^0) \).

Assume that
\[
\exists \rho > 0, \exists a > 0, \forall j, \int_{B(0, \rho)} \int_{\mathbb{R}^3} \|F_j(X)\|^2 dRdr \geq a. \tag{44}
\]

Then, \( E(H_U^0) \leq E(H_0^U) - Ca/\rho \).

**Proof** Since \( Q(H_U^0) = Q(H_0^U) \), we have \( F_j \in Q(H_U^0) \). Hence it suffices to write
\[
q_{H_U^0}(F_j, F_j) = q_{H_0^U}(F_j, F_j) + \int_{\mathbb{R}^3} V(X)||F_j(X)||^2 dX
\leq q_{H_0^U}(F_j, F_j) - \int_{B(0, \rho)} \int_{\mathbb{R}^3} C \rho ||F_j(X)||^2 dX \leq q_{H_0^U}(F_j, F_j) - \frac{C a}{\rho}.
\]
We get the result as \( j \to \infty \). \( \square \)

Now we have to deal with the second case. As stated above, we need to define a new Hamiltonian acting in \( L^2(\mathbb{R}^6) \otimes \mathcal{F}_s \otimes \mathcal{F}_s \). Namely, we define \( \tilde{H}_U^0 \) to be the self-adjoint operator associated with the closed and semi-bounded quadratic form \( q_{\tilde{H}_0^U} \), with domain \( Q(p_1^2 + p_2^2) \cap Q(\tilde{H}_f) \cap Q(U^+) \), such that:
\[
q_{\tilde{H}_0^U}(\Phi, \Psi) = \frac{1}{2m_1}((p_1 - q_1 A_1) \otimes I)\Phi, [(p_1 - q_1 A_1) \otimes I] \Psi
+ \frac{1}{2m_2}((I \otimes (p_2 - q_2 A_2))\Phi, [I \otimes (p_2 - q_2 A_2)] \Psi)
+ (\tilde{H}_f^{1/2} \Phi, \tilde{H}_f^{1/2} \Psi) - ((U^-)^{1/2} \Phi, (U^-)^{1/2} \Psi) + ((U^+)^{1/2} \Phi, (U^+)^{1/2} \Psi), \tag{45}
\]
where we have set $\tilde{H}_f := H_f \otimes I + I \otimes H_f$. Note that in order to show that $q_{\tilde{H}_0}$ is closed, one can follow the subsection 2.3. Then we have:

**Theorem 3.2** Let $(F_j)$ be a normalized sequence in $Q(H_0^0)$ such that $q_{\tilde{H}_0}(F_j, F_j) \to E(H_0^0)$. Assume that

$$\forall n \in \mathbb{N}^*, \exists j_n, \int_{B(0,n)} \int_{\mathbb{R}^3} |F_{j_n}(x)|^2 dR dr \leq \frac{1}{n},$$

(46)

Then $E(H_0^0) < E(\tilde{H}_0^0) \leq E(H_0^0)$.

**Proof** Note that in order to prove that $E(H_0^0) < E(\tilde{H}_0^0)$ with the localization method of [LL], we do not need to assume (46). However, we need it to show that $E(\tilde{H}_0^0) \leq E(H_0^0)$.

We begin with the proof of the first inequality. Since the method is quite similar to prove the second one, we shall not write the details.

**First step: proof of the inequality $E(H_0^0) < E(\tilde{H}_0^0)$**.

To show this inequality, we follow [LL]. Namely, as in theorem 4.3 of [LL], we would like first to find a state $\Psi$ in $Q(\tilde{H}_0^0)$ such that:

- $a)$ the electronic part of $\Psi$ is supported in $B(y_1, R_0) \times B(y_2, R_0)$, that is to say $\Psi(X) = 0$ as soon as $x_1 \notin B(y_1, R_0)$ or $x_2 \notin B(y_2, R_0)$,

- $b)$ the photonic part of $\Psi$ is supported in $B(y_1, L) \times B(y_2, L)$, that is to say the photons of the first component of the tensor product $\mathcal{F}_s \otimes \mathcal{F}_s$ live in $B(y_1, L)$, whereas the photons of the second component live in $B(y_2, L)$,

- $c)$ $\frac{q_{\tilde{H}_0^0}(\Psi, \Psi)}{\|\Psi\|^2} \leq E(\tilde{H}_0^0) + \frac{C_1}{R_0} + \frac{C_2}{(L - 2R_0)^\gamma} \left(\frac{R_0}{L}\right)(1 + |\ln(\Lambda R_0)|)$,

where $R_0 > 0$ and $L > 2R_0$ are fixed, where $C_1$ and $C_2$ are positive constants, and where $\gamma$ is any real number such that $0 < \gamma < 1$.

We start with localizing the electron and the nucleus in balls of radius $R_0$.

**Lemma 3.1** For any fixed $R_0 > 0$, there exists $y_1, y_2 \in \mathbb{R}^3$ and a state $\Psi \in Q(\tilde{H}_0^0)$ such that the electronic part of $\Psi$ is supported in $B(y_1, R_0) \times B(y_2, R_0)$ and

$$\frac{q_{\tilde{H}_0^0}(\Psi, \Psi)}{\|\Psi\|^2} \leq E(\tilde{H}_0^0) + \frac{C_1}{R_0},$$

(47)

where $C_1$ is a positive constant.

**Proof of the lemma**

This lemma is proved in [LL, theorem 4.1]. However in [LL], the authors have to deal with the Pauli principle according to which the states in $\mathcal{H}$ have to be antisymmetric under the exchange of the particles labels. Here the electronic particles are distinct so that we do not have to deal with this problem. Then the proof becomes a bit simpler.

Let $\Psi \in D(\tilde{H}_0^0), \|\Psi\| = 1$ be such that

$$\langle \Psi, \tilde{H}_0^0 \Psi \rangle < E(\tilde{H}_0^0) + \frac{1}{R_0^2},$$
Let \( u \in C_0^{\infty}(\mathbb{R}^3) \) be such that \( 0 \leq u \leq 1 \), \( u = 1 \) in the ball \( B(0, 1/2) \) and \( u = 0 \) outside the ball \( B(0, 1) \). Let us set
\[
u_{1,y}(X) := u \left( \frac{x_1}{R_0} - y \right), \quad \nu_{2,y'}(X) := u \left( \frac{x_2}{R_0} - y' \right),
\]
and note that
\[
\int_{\mathbb{R}^3} u^2(X)dy = \int_{\mathbb{R}^3} u_{2,y'}^2(X)dy' = \int_{\mathbb{R}^3} u^2(z)dz := \beta > 0.
\]
Define \( \Psi_{y,y'} := \frac{1}{\beta} u_{1,y} u_{2,y'} \Psi \); with the definition of \( u \), we easily see that \( \Psi_{y,y'} \in Q(H_U^0) \). Then we have
\[
\int_{\mathbb{R}^6} (\Psi_{y,y'}, \Psi_{y,y'})dydy' = \frac{1}{\beta^2} \int_{\mathbb{R}^6} \int_{\mathbb{R}^3} u_{1,y}^2(X)dy \int_{\mathbb{R}^3} u_{2,y'}^2(X)dy' < \Psi(X), \Psi(X) > dX = (\Psi, \Psi) = 1,
\]
and
\[
q_{H_U^0}(\Psi_{y,y'}, \Psi_{y,y'}) = \frac{1}{\beta^2} (\Psi, \{ |\nabla_{x_1} u_{1,y}|^2 u_{2,y'}^2 + |\nabla_{x_2} u_{2,y'}|^2 u_{1,y}^2 \} \Psi) + \frac{1}{\beta^2} \text{Re}(u_{1,y} u_{2,y'} \Psi, H_U^0 \Psi)
\]
(here \( \text{Re}(z) \) denotes the real part of the complex number \( z \)).

We compute in one hand
\[
\int_{\mathbb{R}^6} (\Psi, (|\nabla_{x_1} u_{1,y}|^2 u_{2,y'}^2 + |\nabla_{x_2} u_{2,y'}|^2 u_{1,y}^2) \Psi)dydy' = \beta \int_{\mathbb{R}^6} \int_{\mathbb{R}^3} \Psi(X), \left( \frac{1}{R_0^2} |(\nabla u)(\frac{x_1}{R_0} - y)|^2 \right) \Psi(X) > dX
\]
\[
+\beta \int_{\mathbb{R}^6} \int_{\mathbb{R}^3} \Psi(X), \left( \frac{1}{R_0^2} |(\nabla u)(\frac{x_2}{R_0} - y')|^2 \right) \Psi(X) > dX' = \frac{2\beta C_0}{R_0^4},
\]
where \( C_0 = \int_{\mathbb{R}^3} |\nabla u(z)|^2dz > 0 \), and in the other hand
\[
\int_{\mathbb{R}^6} (u_{1,y} u_{2,y'} \Psi, H_U^0 \Psi)dydy' = \beta^2 (\Psi, H_U^0 \Psi).
\]

This leads to
\[
\int_{\mathbb{R}^6} \left[ q_{H_U^0}(\Psi_{y,y'}, \Psi_{y,y'}) - (\Psi_{y,y'}, \left( \frac{2C_0}{\beta R_0^2} + 1 \right) E(H_U^0) \Psi_{y,y'}) \right]dydy' = (\Psi, H_U^0 \Psi) - E(H_U^0) < 0.
\]

Therefore \( \exists (y_1, y_2) \in \mathbb{R}^6 \) such that
\[
q_{H_U^0}(\Psi_{y_1,y_2}, \Psi_{y_1,y_2}) < \left[ E(H_U^0) + \frac{\text{Cste}}{R_0^2} \right] (\Psi_{y_1,y_2}, \Psi_{y_1,y_2}),
\]
and in particular, \( \Psi_{y_1,y_2} \neq 0 \) (here we have set \( \text{Cste} = 1 + 2C_0\beta \)).

\( \square \)

**Back to the proof of the inequality** \( E(H_U^0 \Psi) < E(H_U^0) \).

Now, we have to localize the photons around the nucleus and the electron. We do not write the details of the proof here but sketch only it; we refer once again to [LL, lemma 4.3].
First, replacing the Laplacian by the Dirichlet Laplacian, \( \tilde{H}_U^0 \) is seen as an operator acting in \( L^2(B(y_1, R) \times B(y_2, R_0); \mathcal{F}_s \otimes \mathcal{F}_s) \). We can show that this operator (that we call \( \tilde{H}_U^0 \)) has a ground state \( \Phi_D \), so that in particular

\[
(\Phi_D, \tilde{H}_U^0 \Phi_D) \leq q_{\tilde{H}_U^0}(\Psi_{y_1,y_2}, \Psi_{y_1,y_2}) \leq E(\tilde{H}_U^0) + \frac{\text{Cste}}{R_0^2},
\]

where \( \Psi_{y_1,y_2} \) is the (normalized) state given by lemma 3.1, which satisfies the Dirichlet boundary conditions.

Note that the Hamiltonian \( \tilde{H}_U^0 \) is defined in the same way as \( \tilde{H}_U^0 \) in (45); the only modification is that the domain of the quadratic form associated with \( \tilde{H}_U^0 \) in \( H^1_0(B(y_1, R_0) \times B(y_2, R_0); \mathcal{F}_s \otimes \mathcal{F}_s) \) instead of \( H^1_0(\mathbb{R}^6; \mathcal{F}_s \otimes \mathcal{F}_s) \). In particular if we set \( \Phi_D(X) = 0 \) outside \( B(y_1, R_0) \times B(y_2, R_0) \), then \( \Phi_D \in Q(\tilde{H}_U^0) \).

Therefore we would like to localize the photons in the state \( \Phi_D \).

Recall from section 2.1 that any state \( \Psi \in L^2(\mathbb{R}^6; \mathcal{F}_s \otimes \mathcal{F}_s) \) can be written as \( \Psi : X \mapsto \Psi(X) \) with

\[
\Psi(X) = \sum_{n \geq 0} \sum_{i_1 < \cdots < i_n} \sum_{p_1, \ldots, p_n} \Psi_{i_1, p_1; \ldots; i_n, p_n}(X) |i_1, p_1; \ldots; i_n, p_n\rangle f \otimes |i'_1, p'_1; \ldots; i'_n, p'_n\rangle f,
\]

where

\[
|i_1, p_1; \ldots; i_n, p_n\rangle f = \frac{1}{\sqrt{p_1! \cdots p_n!}} a^*(f_{i_1})^{p_1} \cdots a^*(f_{i_n})^{p_n} \Omega,
\]

and where \( (f_i) \) is an orthonormal basis of \( L^2(\mathbb{R}^3; \mathbb{C}) \).

Then the operator \( J_L \) will be defined by

\[
J_L (|i_1, p_1; \ldots; i_n, p_n\rangle f \otimes |i'_1, p'_1; \ldots; i'_n, p'_n\rangle f)
= \frac{1}{\sqrt{p_1! \cdots p_n!}} \frac{1}{\sqrt{p'_1! \cdots p'_n!}} a^*(h_1 f_{i_1})^{p_1} \cdots a^*(h_1 f_{i_n})^{p_n} \Omega \otimes a^*(h_2 f_{i'_1})^{p'_1} \cdots a^*(h_2 f_{i'_n})^{p'_n} \Omega,
\]

where the functions \( h_1, h_2 \in C_0^\infty(\mathbb{R}^3) \) are defined by

\[
\begin{cases}
  0 \leq h_1 \leq 1 \text{ and } 0 \leq h_2 \leq 1, \\
  h_1 = 1 \text{ in the ball } B(y_1, L/2) \text{ and } h_2 = 1 \text{ in the ball } B(y_2, L/2), \\
  h_1 = 0 \text{ outside the ball } B(y_1, L) \text{ and } h_2 = 0 \text{ outside the ball } B(y_2, L).
\end{cases}
\]

In other words, \( h_1 \) localize photons next to the particle \( x_1 \) (which lives in \( B(y_1, R_0) \)) and \( h_2 \) localize photons next to the particle \( x_2 \) (which lives in \( B(y_2, R_0) \)).

Next we set \( \Psi_0 := J_L \Phi_D / ||J_L \Phi_D||^2 \). Since \( \Phi_D \in Q(\tilde{H}_U^0) \), we easily see that \( \Psi_0 \in Q(\tilde{H}_U^0) \).

Following [LL], theorem 4.3, we can show that

\[
\frac{q_{\tilde{H}_U^0}(J_L \Phi_D, J_L \Phi_D)}{||J_L \Phi_D||^2} \leq E(\tilde{H}_U^0) + \frac{C_1}{R_0^2} + \frac{C_2}{(L - 2R_0)^\gamma} (R_0 \text{ ln}(A R_0))^\gamma, \quad (R_0 > 0, \gamma > 1)
\]

for any \( 0 < \gamma < 1 \) and where \( C_1, C_2 > 0 \).

Note that we can use here some invariance of the Hamiltonian \( \tilde{H}_U^0 \) to simplify the proof of the last inequality. Namely, if we set

\[
T_t = e^{it \frac{\Delta}{2}} (p_1 + d\Gamma(-i\nabla)) \otimes e^{-it \frac{\Delta}{2}} (p_2 + d\Gamma(-i\nabla)),
\]

then...
we can see that for all \( t \in \mathbb{R}^3 \) and all \( \Phi \in Q(\bar{H}_0) \):

\[
q\bar{H}_0(T_t \Phi, T_t \Phi) = q\bar{H}_0(\Phi, \Phi).
\]  

(53)

In other words, if one translates the electron (with its cloud of photons) and the nucleus (with its cloud of photons) without moving the position of the center of mass, one does not modify the energy of the state under consideration.

We take \( t = 3L - (y_1 - y_2) \) and we replace \( \Psi_0 \) by \( \Psi_0 := T_t J_L \Phi_D / \| J_L \Phi_D \|^2 \), so that the new state \( \Psi_0 \) has the same properties as the previous one, except that in the new state a distance \( L \) separate the two balls where the particles live. Thus we do not have to pay any attention to the fact that the balls may overlap or not (as it is done in [LL, lemma 6.1]).

Finally we would like to find a state \( \Xi \in Q(H_0^\nu) \) whose energy in \( H_0^\nu \) would be sufficiently close to \( q\bar{H}_0(\Psi_0, \Psi_0) \). Then the term \( (\Xi, V\Xi) \) would be the main term in \( q\bar{H}_0(\Xi, \Xi) \) and we would be able to conclude.

We shall apply formulae of the type (2.24) of [LL], so that it is convenient to replace \( A(x_i)^2 \) with the normal-ordered : \( A(x_i)^2 \) : in the definitions of the Hamiltonians \( H_0^\nu \) and \( \bar{H}_0^\nu \). We write the "normal-ordered Hamiltonians" as : \( \bar{H}_0^\nu \) : and : \( H_0^\nu \) : respectively. We easily see that \( E(: \bar{H}_0^\nu : ) - E(: H_0^\nu : ) = E(\bar{H}_0^\nu ) - E(H_0^\nu) \).

Now, let \( (f_k) \) be an orthonormal basis of \( L^2(B(y_1, L); \mathbb{C}^2) \) and let \( (g_l) \) be an orthonormal basis of \( L^2(B(y_2, L); \mathbb{C}^2) \). We know that

- \( \left\{ |i_1, p_1; \ldots; i_n, p_n \rangle = \frac{1}{\sqrt{p_1 \cdots p_n}} a^*(f_{i_1}) p_1 \cdots a^*(f_{i_n}) p_n \Omega, n \in \mathbb{N}, i_k, p_k \in \mathbb{N} \right\} \) is an orthonormal basis of \( F_n(L^2(B(y_1, L); \mathbb{C}^2)) \),
- \( \left\{ |i'_1, p'_1; \ldots; i'_{n'}, p'_{n'} \rangle = \frac{1}{\sqrt{p'_1 \cdots p'_{n'}}} a^*(g_{i'_1}) p'_1 \cdots a^*(g_{i'_{n'}}) p'_{n'} \Omega, n' \in \mathbb{N}, i'_{k'}, p'_{k'} \in \mathbb{N} \right\} \) is an orthonormal basis of \( F_n(L^2(B(y_2, L); \mathbb{C}^2)) \).

So we can write \( \Psi_0 \) as

\[
\Psi_0(X) = \sum_{n \geq 0} \sum_{\alpha \geq 0} \sum_{i_1 < i_2 < \cdots < i_n} \sum_{p_1 \cdots p_n} \Psi_{i_1, p_1; \ldots; i_n, p_n} (X) |i_1, p_1; \ldots; i_n, p_n \rangle \otimes |i'_1, p'_1; \ldots; i'_{n'}, p'_{n'} \rangle.
\]

where \( \Psi_{i_1, p_1; \ldots; i_n, p_n} \in L^2(\mathbb{R}^6) \), and

\[
\sum_{n \geq 0} \sum_{\alpha \geq 0} \sum_{i_1 < i_2 < \cdots < i_n} \sum_{p_1 \cdots p_n} \int_{\mathbb{R}^6} \left| \Psi_{i_1, p_1; \ldots; i_n, p_n} (X) \right|^2 dX = 1.
\]

Pick an orthonormal basis \( \{ e_l \} \) of \( L^2(\mathbb{R}^3) \) in \( H^2(\mathbb{R}^3) \). Thus, we can also write \( \Psi_{i_1, p_1; \ldots; i_n, p_n} \) as

\[
\Psi_{i_1, p_1; \ldots; i_n, p_n} (X) = \sum_{l \geq 0} \Psi_{L_{i_1, p_1; \ldots; i_n, p_n}, l} e_l(x_1) e_l(x_2).
\]

17
Then we can compute:

\[ q, R^v_\ell (\Psi_0, \Psi_0) = \frac{1}{2m_1} \sum_{n,i,p,l,o,j,q,m} \frac{\psi^{m, m'}_{j_1, p_1; \ldots; j_n, p_n} \psi^{m, m'}_{j, q; \ldots; j_n, q_n}}{\delta_{l, 1} \delta(l, q; \ldots; q_n)} \times \nabla \psi_{m, m'} \delta(i_1, p_1; \ldots; i_n, p_n) |j_1, q; \ldots; j_n, q_n) dx_1 \]

\[ \int_{\mathbb{R}^3} \langle e_I(x_1)|i_1, p_1; \ldots; i_n, p_n \rangle f_j : (p_1 - q_1 A(x_1))^2 : e_{m_n}(x_1)|j_1, q_1; \ldots; j_n, q_n \rangle f \rangle dx_1 \]

\[ + \frac{1}{2m_2} \sum_{n,i,p,l,o,j,q,m} \frac{\psi^{m, m'}_{j_1, p_1; \ldots; j_n, p_n} \psi^{m, m'}_{j, q; \ldots; j_n, q_n}}{\delta_{l, 1} \delta(l, q; \ldots; q_n)} \times \nabla \psi_{m, m'} \delta(i_1, p_1; \ldots; i_n, p_n) |j_1, q_1; \ldots; j_n, q_n) g \rangle dx_1 \]

\[ \int_{\mathbb{R}^3} \langle e_I(x_2)|i_1', p_1'; \ldots; i_n', p_n' \rangle g : (p_2 - q_2 A(x_2))^2 : e_{m_n'}(x_2)|j_1', q_1'; \ldots; j_n', q_n') g \rangle dx_2 \]

\[ + \sum_{n,i,p,l,o,j,q,m} \frac{\psi^{m, m'}_{j_1, p_1; \ldots; j_n, p_n} \psi^{m, m'}_{j, q; \ldots; j_n, q_n}}{\delta_{l, 1} \delta(l, q; \ldots; q_n)} \times \nabla \psi_{m, m'} \delta(i_1, p_1; \ldots; i_n, p_n) |j_1, q_1; \ldots; j_n, q_n) g \rangle dx_1 \]

Here \( \delta \) denotes the Kronecker symbol.

Now, we define the state \( \Xi \in \mathcal{L}^2(\mathbb{R}^6; \mathcal{F}_s) \) as

\[ \Xi(X) = \sum_{n=0}^{\infty} \sum_{i_1 \leq i_2 \leq \ldots \leq i_n} \sum_{p_1 \ldots p_n} \psi^{m, m'}_{j_1, p_1; \ldots; j_n, p_n} (X)|i_1, p_1; \ldots; i_n, p_n \rangle f \otimes |i_1', p_1'; \ldots; i_n', p_n' \rangle g, \]

with

\[ |i_1, p_1; \ldots; i_n, p_n \rangle f \otimes |i_1', p_1'; \ldots; i_n', p_n' \rangle g := \frac{1}{\sqrt{|p_1|! \cdots |p_n|!}} \sum_{\alpha} a^*(f_\alpha) p_1^\alpha a^*(f_\alpha') p_1'^\alpha \cdots a^*(g_\alpha) p_n^\alpha a^*(g_\alpha') p_n'^\alpha \Omega. \]

In particular we can see that \( \Xi \in Q(H^0) \) and that \( ||\Xi|| = ||\Psi_0|| = 1. \)

Thus, applying formulae of the type (2.24) of [LL] to the states

\[ |i_1, p_1; \ldots; i_n, p_n \rangle f \otimes |i_1', p_1'; \ldots; i_n', p_n' \rangle g, \]

we get

\[ q, H^0 (\Xi, \Xi) = [1] + [2] + [3] + [4] + [5], \]

with
\[ [1] = \frac{1}{2m_1} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{m'm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} \langle e_1(x) | i_1, p_1; \ldots; i_n, p_n \rangle f \cdot (p_1 - q_1 A(x)) \rangle^2 : c_m(x) | j_1, q_1; \ldots; j_m, q_m \rangle \rangle dx_1 \]
\[ + \frac{1}{2m_2} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} \langle e_2(x) | i_1', p_1'; \ldots; i_n', p_n' \rangle g \cdot (p_2 - q_2 A(x)) \rangle^2 : c_{m'}(x) | j_1', q_1'; \ldots; j_m', q_m' \rangle \rangle dx_2 \]
\[ + \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} e_1(x) e_2(x) (e_1(x) c_m(x) e_{m'}(x_2) dx_1 dx_2 \]
\[ + \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} U(R) c_1(x) e_2(x) c_m(x) e_{m'}(x_2) dx_1 dx_2 \]
\[ + \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} V(r) c_1(x) e_2(x) c_m(x) e_{m'}(x_2) dx_1 dx_2 \]
\[ [2] = -\frac{q_1}{m_1} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} e_1(x) (p_1 c_m(x)) (e_1(x) c_m(x) | i_1, p_1; \ldots; i_n, p_n \rangle g \cdot A(x) | j_1, q_1; \ldots; j_m, q_m \rangle \rangle dx_1 \]
\[ + \frac{q_2}{m_2} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} e_2(x) (p_2 c_m(x)) (e_2(x) c_m(x) | i_1, p_1; \ldots; i_n, p_n \rangle f \cdot A(x) | j_1, q_1; \ldots; j_m, q_m \rangle \rangle dx_2 \]
\[ [3] = \frac{q_1^2}{2m_1} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} e_1(x) c_m(x) (e_1(x) c_m(x) | i_1, p_1; \ldots; i_n, p_n \rangle \cdot | x_1 \rangle^2 : | j_1, q_1; \ldots; j_m, q_m \rangle \rangle dx_1 \]
\[ + \frac{q_2^2}{2m_2} \sum_{n,i,p,o,j,q,m} \sum_{o,j,q,m} \Psi_{i_1, p_1, \ldots, i_n, p_n}^{m,m'} \Psi_{j_1, q_1, \ldots, j_m, q_m}^{m,m'} \delta_{lm} \delta_{\langle i_1, p_1, \ldots, i_n, p_n \rangle} \langle j_1, q_1, \ldots, j_m, q_m \rangle \times \int_{R^3} e_2(x) c_m(x) (e_2(x) c_m(x) | i_1, p_1; \ldots; i_n, p_n \rangle \cdot | x_2 \rangle^2 : | j_1, q_1; \ldots; j_m, q_m \rangle \rangle dx_2 \]
\[ [4] = \frac{q}{m} \sum_{n,i,p,l} \sum_{a,j,q,m} \psi^{l'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \psi^{m'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \delta_{lm} \times \\
\int_{\mathbb{R}^3} \tilde{e}(x_1) e_m(x_1) |i_1, p_1; \ldots; i_n, p_n, f, A(x_1)|j_1, q_1; \ldots; j_0, q_0, f \rangle \\
\times \langle i_1', p_1'; \ldots; i_n', p_n', g, A(x_1)|j_1', q_1'; \ldots; j_0', q_0', g \rangle dx_1 \\
+ \frac{q}{m^2} \sum_{n,i,p,l} \sum_{a,j,q,m} \psi^{l'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \psi^{m'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \delta_{lm} \times \\
\int_{\mathbb{R}^3} \tilde{e}(x_2) e_m(x_2) |i_1, p_1; \ldots; i_n, p_n, f, A(x_2)|j_1, q_1; \ldots; j_0, q_0, f \rangle \\
\times \langle i_1', p_1'; \ldots; i_n', p_n', g, A(x_2)|j_1', q_1'; \ldots; j_0', q_0', g \rangle dx_2, \]

\[ [5] = \sum_{n,i,p,l} \sum_{a,j,q,m} \psi^{l'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \psi^{m'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \delta_{lm} \times \\
\left[ \sum_{\lambda} \int_{\mathbb{R}^3} |k| \langle \tilde{\alpha}_\lambda(k)|i_1, p_1; \ldots; i_n, p_n, f, j_1, q_1; \ldots; j_0, q_0, f \rangle \\
\times \langle i_1', p_1'; \ldots; i_n', p_n', g, \tilde{\alpha}_\lambda(k)|j_1', q_1'; \ldots; j_0', q_0', g \rangle dk \\
+ \sum_{\lambda} \int_{\mathbb{R}^3} |k| \langle i_1; \ldots; i_n, p_n, f, \tilde{\alpha}(k)|j_1, q_1; \ldots; j_0, q_0, f \rangle \\
\times \langle \tilde{\alpha}_\lambda(k)|i_1', p_1', \ldots; i_n', p_n', g, j_1', q_1'; \ldots; j_0', q_0' \rangle dk \right]. \]

We see that \([1]\) equals \(q \tilde{\rho}_{\Psi_0}^\gamma(\Psi_0, \Psi_0) - (-V)^{1/2}\Psi_0, (-V)^{1/2}\Psi_0)\).

Moreover, \([3]\) is less than \(\text{Cte}/L^{2\gamma}\) according to \([LL, \text{lemma } 5.6]\).

Finally we can assume \([2] + [4] + [5] \leq 0\) because if we replace \(\Xi\) by \(\tilde{\Xi}\) where

\[ \tilde{\Xi}(X) = \sum_{n=0}^{\infty} \sum_{n' \geq 0} \sum_{\epsilon} \sum_{\epsilon'} \psi^{l'}_{j_1, q_1, \ldots, j_n, q_n, p_1, \ldots, p_m, \epsilon} \times \\
\frac{1}{\rho_1 \cdots \rho_n} (-a^*(f_i))^{p_1} \ldots (-a^*(f_i))^{p_m} \Omega \phi, \]

with

\[ |i_1, p_1; \ldots; i_n, p_n, f\rangle^{-} := \frac{1}{\sqrt{\rho_1 \cdots \rho_n}} (-a^*(f_i))^{p_1} \ldots (-a^*(f_i))^{p_m} \Omega, \]

then \([1]\) and \([3]\) do not change whereas \([2],[4]\) and \([5]\) are replaced by their opposite terms.

Now in the state \(\Psi_0\) (and also in the state \(\Xi\)), the particle \(x_1\) is localized in \(B(y_1, R_0) \subset B(y_1, L)\), whereas \(x_2\) is localized in \(B(y_2, R_0) \subset B(y_2, L)\), and we have chosen \(y_1, y_2\) such that
the distance between the two balls \( B(y_1, L) \) and \( B(y_2, L) \) is \( L \). Therefore \( \Psi_0 \) is supported in \( \{ \nu \mid \leq 5L \} \), which yields
\[
-((V)^{1/2}\Psi_0, (V)^{1/2}\Psi_0) \leq -\frac{C}{5L}(\Psi_0, \Psi_0) = -\frac{C}{5L}
\]
Here (53) is crucial because otherwise the balls \( B(y_1, L) \) and \( B(y_2, L) \) could be far away from each other and we could not estimate \( ((V)^{1/2}\Psi_0, (V)^{1/2}\Psi_0) \).

To conclude, (51) yields
\[
q_{H_0^\gamma}(\Xi, \Xi) \leq E(H_0^\gamma) + \frac{C_1}{R_0^2} + \frac{C_2}{(L-2R_0)^\gamma} \left( \frac{R_0}{L^\gamma} \right) (1 + |\ln(A\nu_0)|) + \frac{C_3}{L^{2\gamma}} - \frac{C}{5L},
\]
for all \( \gamma < 1 \), all \( R_0 > 0 \) and all \( L > 2R_0 \).

We choose \( \gamma \) such that \( \frac{3}{4} < \gamma < 1 \), and \( R_0 = L^\alpha \) with \( \frac{1}{2} < \alpha < 2\gamma - 1 \). Then, for \( L \) large enough, \( C/L \) becomes the dominant term in the last inequality, that is to say
\[
\frac{C_1}{R_0^2} + \frac{C_2}{(L-2R_0)^\gamma} \left( \frac{R_0}{L^\gamma} \right) (1 + |\ln(A\nu_0)|) + \frac{C_3}{L^{2\gamma}} - \frac{C}{5L} < 0.
\]
Thus
\[
E(H_0^\gamma) < E(\tilde{H}_0^\gamma)
\]
and the proof is complete.

**Second step: proof of the inequality** \( E(\tilde{H}_0^\gamma) \leq E(H_0^\gamma) \).

The proof uses again the localization methods of \([LL]\) and we only sketch it. Let us note yet that the localization errors need not to be estimate as precisely as in the previous step. We only need to know that these corrections can be made as small as we want.

Recall that the assumption (46) tells us that there exists a normalized minimizing sequence for \( H_0^\gamma, (F_j) \), which verifies:
\[
\forall n \in \mathbb{N}^*, \exists j_n, \int_{B(\emptyset, n)} \int_{\mathbb{R}^3} \|F_{j_n}(X)\|^2 dR dr \leq \frac{1}{n}, \tag{57}
\]

Let \( \tau_n \) and \( \nu_n \) be functions defined by
\[
\begin{cases}
\tau_n(r) = 1 \text{ if } |r| \leq n - \frac{1}{2} \\
\nu_n(r) = 1 \text{ if } |r| \geq n \\
\tau_n(r) = \tau\left(\frac{|r|-(n-1)}{\nu}\right) \text{ and } \nu_n(r) = \nu\left(\frac{|r|-(n-1)}{\nu}\right) \text{ if } n - \frac{1}{2} \leq |r| \leq n,
\end{cases}
\]

where \( \tau \) and \( \nu \) are defined on \( 1/2 \leq |r| \leq 1 \) and are independent on \( n \)
\[
\begin{cases}
0 \leq \nu_n \leq 1 \text{ and } 0 \leq \tau_n \leq 1 \\
\nu_n, \tau_n \in C^\infty(\mathbb{R}^3) \\
\nu_n^2 + \tau_n^2 = 1.
\end{cases}
\]

Then we have \( \tau_n F_{j_n}, \nu_n F_{j_n} \in Q(H_0^\gamma) \) and
\[
q_{H_0^\gamma}(F_{j_n}, F_{j_n}) = q_{H_0^\gamma}(\tau_n F_{j_n}, \tau_n F_{j_n}) + q_{H_0^\gamma}(\nu_n F_{j_n}, \nu_n F_{j_n}) - (F_{j_n}, (|\nabla \tau_n|^2 + |\nabla \nu_n|^2) F_{j_n}),
\]
with
\[
(F_{j_n}, (|\nabla \tau_n|^2 + |\nabla \nu_n|^2) F_{j_n}) = \int_{\{n - \frac{1}{2} \leq |r| \leq n\}} (|\nabla \tau(r)|^2 + |\nabla \nu(r)|^2) \int_{\mathbb{R}^3} \|F_{j_n}(X)\|^2 dR dr \leq \frac{\text{Cste}}{n},
\]
so that
\[ q_{H^0_U} (v_n F_{j^n}, v_n F_{j^n}) - E(H^0_U) (v_n F_{j^n}, v_n F_{j^n}) \leq q_{H^0_U} (F_{j^n}, F_{j^n}) - E(H^0_U) + \frac{\text{Cste}}{n}. \] (58)

Since
\[ 1 \geq \|v_n F_{j^n}\|^2 \geq \int_{B(0,n)^c} \int_{\mathbb{R}^3} \|F_{j^n}(X)\|^2 dR dr \geq 1 - \frac{1}{n}, \]
this shows that \( v_n F_{j^n} / \|v_n F_{j^n}\| \) is a normalized minimizing sequence for \( H^0_U \).

Then, we note again \( v_n F_{j^n} = F_{j^n} / \|v_n F_{j^n}\| \), and we localize the particles in this state. More precisely, we pick \( R_0 > 0 \) and \( L > 0 \) such that \( L - 2R_0 > 0 \). Then there exists \( n_0 \) such that for all \( n \geq n_0, v_n F_{j^n}(X) = 0 \) on \( \{ X, |r| \leq 3L \} \). Next, with the help of [LL], starting with \( v_n F_{j^n} \) (for \( n \) large enough), we can construct a normalized state \( \Xi_n \) in \( Q(H^0_U) \) such that

1. the electronic part of \( \Xi_n \) is supported in \( B(y_1, R_0) \times B(y_2, R_0) \),
2. the photonic part of \( \Xi_n \) is supported in \( B(y_1, L) \cup B(y_2, L) \),
3. \( q_{H^0_U} (\Xi_n, \Xi_n) \leq E(H^0_U) + \frac{C_1}{R_0} + \frac{C_2}{(L - 2R_0)^7} \left( \frac{R_0}{L^7} \right) (1 + |\ln(A R_0)|) \)

where \( C_1 \) and \( C_2 \) are positive constants, and where \( \gamma \) is any real number such that \( 0 < \gamma < 1 \).

In addition, the distance between the balls \( B(y_1, L) \) and \( B(y_2, L) \) is at least \( L \) by construction.

The proof to get this result is close to the one of the first step, that is we localize first the nucleus and the electron in the state \( v_n F_{j^n} \). Next, we replace the Laplacian with the Dirichlet Laplacian, which defines a new Hamiltonian that has a ground state. Finally, we localize the photons around the electron and the nucleus in this ground state. Note that the operator \( J_L \) that allows us to localize the photons is defined here by:

\[ J_L a^*(h_{i_1})p_{i_1} \ldots a^*(h_{i_p})p_{i_p} \Omega := a^*(hh_{i_1})p_{i_1} \ldots a^*(hh_{i_p})p_{i_p} \Omega, \] (59)

where \( 0 \leq h \leq 1 \) is a function in \( C_0^\infty (\mathbb{R}^3) \) that is equal to 1 on \( B(y_1, L/2) \cup B(y_2, L/2) \) and that is equal to 0 outside \( B(y_1, L) \cup B(y_2, L) \).

Thus, we have \( h = h|_{B(y_1, L)} + h|_{B(y_2, L)} \), and we can write \( \Xi_n \) as

\[ \Xi_n(X) = \sum_{i_1, p_{i_1}, \ldots, i_p, p_{i_p}} \Xi_{i_1, p_{i_1}, \ldots, i_p, p_{i_p}}(X) a^*(f_{i_1})p_{i_1} \ldots a^*(f_{i_p})p_{i_p} a^*(g_{i'_1})p_{i'_1} \ldots a^*(g_{i'_p})p_{i'_p} \Omega, \]

where \( f_{i_k} \) is supported in \( B(y_1, L) \) and \( g_{i'_k} \) is supported in \( B(y_2, L) \). In other words, all the factors \( a^*(h|_{B(y_1, L)})f \) are put on the left whereas the factors \( a^*(h|_{B(y_2, L)})f \) are put on the right.

Now, we can define \( \Psi_n \) in \( L^2(\mathbb{R}^3; F_0 \otimes F_0) \) by

\[ \Psi_n(X) := \sum_{i_1, p_{i_1}, \ldots, i_p, p_{i_p}} \Xi_{i_1, p_{i_1}, \ldots, i_p, p_{i_p}}(X) a^*(f_{i_1})p_{i_1} \ldots a^*(f_{i_p})p_{i_p} \Omega \otimes a^*(g_{i'_1})p_{i'_1} \ldots a^*(g_{i'_p})p_{i'_p} \Omega. \]

The same computations as the ones of the previous step yield

\[ q_{H^0_U} (\Psi_n, \Psi_n) \leq E(H^0_U) + \varepsilon \]

for all \( n \) large enough, where \( \varepsilon \) depends on \( R_0, L \) and \( \gamma \) but can be made as small as we want.

Note that, contrary to what we did in (55), it is useless to replace \( \Psi_n \) with a state \( \bar{\Psi}_n \) in order to eliminate some terms, since these terms are small when \( R_0 \) and \( L \) are large.

This shows that \( E(H^0_U) \leq E(H^0_U) + \varepsilon \), where \( \varepsilon \) can be made as small as we want. Thus the proof is complete. \[ \square \]
4 Existence of a ground state for $H_U^V$

In this section we shall prove the existence of a ground state for the Hamiltonian $H_U^V$. The proof follows the one in [GLL]. Namely, the existence of a ground state $\Phi_m$ is proved first for the massive Hamiltonian $H_U^V(m)$. Next it is shown that $\Phi_m$ decays exponentially in $X$, so that Theorems 6.1 and 6.3 of [GLL] concerning $\|\hat{a}_\lambda(k)\Phi_m\|$ and $\|\nabla_k \hat{a}_\lambda(k)\Phi_m\|$ follow. Finally the Rellich-Kondrachov theorem shows that the weak limit of $\Phi_m$ (when $m \to 0$) is a ground state for $H_U^V$.

4.1 Existence of a ground state for $H_U^V(m)$

As in [GLL], the proof is divided into two steps: the first step is to find a sufficient condition in order to get the existence of a ground state. Namely, it is sufficient to show that for all normalized sequence $(\Psi^j) \in Q(H_U^V(m))$ which converges weakly to 0 and such that $q_{H_U^V(m)}(\Psi^j, \Psi^j)$ is uniformly bounded, we have

$$\liminf_{j \to \infty} q_{H_U^V(m)}(\Psi^j, \Psi^j) > E(H_U^V(m)).$$

(60)

The second step is to prove that the condition (60) is satisfied. This follows again from the localization methods of [GLL], with some slight modifications.

**Theorem 4.1** For all $m > 0$ small enough, $\exists \Phi_m \in D(H_U^V(m))$ such that $\|\Phi_m\| = 1$ and $H_U^V(m)\Phi_m = E(H_U^V(m))\Phi_m$.  

**Proof** First step

Assume that (60) is satisfied and let us show that a ground state exists for $H_U^V(m)$. Let $(\Phi^j) \in Q(H_U^V(m))$ be a normalized sequence such that

$$ q_{H_U^V(m)}(\Phi^j, \Phi^j) \to_{j \to \infty} E(H_U^V(m)). $$

Since $(\Phi^j)$ and $([H_U^V(m) - E(H_U^V(m))]^{1/2} \Phi^j)$ are bounded sequences, they converge weakly along some subsequences to limits denoted by $\Phi_m$ and $\Phi'_m$ respectively. These subsequences are still denoted by $(\Phi^j)$ and $([H_U^V(m) - E(H_U^V(m))]^{1/2} \Phi^j)$. Then we have

$$ (\phi, [H_U^V(m) - E(H_U^V(m))]^{1/2} \Phi^j) = ([H_U^V(m) - E(H_U^V(m))]^{1/2} \phi, \Phi^j), $$

for all $\phi \in Q(H_U^V(m))$. When $j \to \infty$, this leads to

$$ (\phi, \Phi'_m) = ([H_U^V(m) - E(H_U^V(m))]^{1/2} \phi, \Phi_m). $$

Therefore $\Phi_m \in Q(H_U^V(m))$ and $[H_U^V(m) - E(H_U^V(m))]^{1/2} \Phi_m = \Phi'_m$.

Then, setting $\Psi^j = \Phi^j - \Phi_m$ as in [GLL], we have $\Psi^j \to 0$ and $[H_U^V(m) - E(H_U^V(m))]^{1/2} \Psi^j \to 0$, 

23
Thus so that

\[
0 = \lim_{j \to \infty} q_{H_U^V(m)}(\Psi^j, \Phi^j) - E(H_U^V(m))(\Phi^j, \Phi^j)
\]

\[
= \lim_{j \to \infty} \left( \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2}(\Phi_m + \Psi^j), \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2}(\Phi_m + \Psi^j) \right)
\]

\[
= \left( \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Phi_m, \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Phi_m \right)
\]

\[
+ \lim_{j \to \infty} \left( \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Psi^j, \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Psi^j) \right).
\]

Thus \( \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Phi_m = 0 \) and \( \lim_{j \to \infty} \left[ H_U^V(m) - E(H_U^V(m)) \right]^{1/2} \Psi^j \right) = 0 \). Together with (60), this leads to \( \Psi^j \to 0 \) strongly, so that \( \|\Phi_m\| = 1 \).

Finally \( \|\Phi_m\| = 1, \Phi_m \in D(H_U^V(m)) \) and \( H_U^V(m)\Phi_m = E(H_U^V(m))\Phi_m \).

**Second step**

Let \( \langle \Psi^j \rangle \in Q(H_U^V(m)) \) be a normalized sequence which converges weakly to 0 and such that \( q_{H_U^V(m)}(\Psi^j, \Psi^j) \) is uniformly bounded. Let us show that

\[
\liminf_{j \to \infty} q_{H_U^V(m)}(\Psi^j, \Psi^j) > E(H_U^V(m)).
\]

Let \( \phi_1, \phi_2, \phi_3 \in C^\infty(\mathbb{R}^6) \) be such that

\[
\begin{align*}
\phi_1 &= 1 \text{ on the set } \{ X \in \mathbb{R}^6, |r| \leq 1, |R| \leq 1 \}, \\
\phi_2 &= 0 \text{ on } \{ X \in \mathbb{R}^6, |r| \geq 2 \} \cup \{ X \in \mathbb{R}^6, |R| \geq 2 \}, \\
\phi_3 &= 0 \text{ on } \{ X \in \mathbb{R}^6, |r| \leq 1 \}, \\
\phi_2 &= 1 \text{ on } \{ X \in \mathbb{R}^6, |r| \geq 2 \}, \\
\phi_3 &= 1 \text{ on } \{ X \in \mathbb{R}^6, |r| \leq 1, |R| \geq 2 \}, \\
\phi_3 &= 0 \text{ on } \{ X \in \mathbb{R}^6, |r| \geq 2 \} \cup \{ X \in \mathbb{R}^6, |R| \leq 1 \}, \\
\phi_3 &= 0 \text{ on } \{ X \in \mathbb{R}^6, |r| \leq 1 \}, \\
0 &\leq \phi_1 \leq 1,
\end{align*}
\]

and \( \phi_1^2 + \phi_2^2 + \phi_3^2 = 1 \).

Moreover we set \( \phi_{i,T}(X) = \phi_i(X/T) \) for all \( T > 0 \) and \( i = 1, 2, 3 \). Then, \( \phi_{i,T}\Psi^j \in Q(H_U^V(m)) \), and we can show

\[
q_{H_U^V(m)}(\Psi^j, \Psi^j) = \sum_{i=1, 2, 3} q_{H_U^V(m)}(\phi_{i,T}\Psi^j, \phi_{i,T}\Psi^j) - \sum_{i=1, 2, 3} (\Psi^j, |\nabla \phi_{i,T}|^2 \Psi^j),
\]

where \( \nabla \) is the gradient vector in \( \mathbb{R}^6 \).

Note that \( |\nabla \phi_i| \leq C_i \) where \( C_i \) is a positive constant. Therefore

\[
- \sum_{i=1, 2, 3} (\Psi^j, |\nabla \phi_{i,T}|^2 \Psi^j) \geq - \frac{C_{ste}}{T^2}.
\]

24
Now, let us estimate \( q_{H^V_2(m)}(\phi_1, T \Psi^j, \phi_1, T \Psi^j) \). Here, the Hamiltonian \( \tilde{H}^V_2(m) \) is defined in the same way as in (45), as an operator acting in \( L^2(\mathbb{R}^6; F_s \otimes F_s) \), to be the self-adjoint operator associated with the quadratic form with domain \( Q(p_2^2 + p_2^2) \cap Q(U^+) \cap Q(\tilde{H}_f(m)) \):

\[
q_{\tilde{H}^V_2(m)}(\Phi, \Psi) = \frac{1}{2m_1} \left( [(p_1 - q_1 A_1) \otimes I] \Phi, [(p_1 - q_1 A_1) \otimes I] \Psi \right)
+ \frac{1}{2m_2} \left( [(p_2 - q_2 A_2) \otimes I] \Phi, [(p_2 - q_2 A_2) \otimes I] \Psi \right)
+ (\tilde{H}_f(m))^{1/2} \Phi, (\tilde{H}_f(m))^{1/2} \Psi
- (-V)^{1/2} \Phi, (-V)^{1/2} \Psi
- (U^--)^{1/2} \Phi, (U^--)^{1/2} \Psi
+ (U^+)^{1/2} \Phi, (U^+)^{1/2} \Psi,
\]

where we have set \( \tilde{H}_f(m) := H_f(m) \otimes I + I \otimes H_f(m) \). Note that, on \( C_0^\infty(\mathbb{R}^6) \otimes D_S \otimes D_S \), we have

\[
\tilde{H}^V_2(m) = H^V_2(m) \otimes I + I \otimes H_f(m).
\]

Since \( H_f(m) \geq mI - mP_1 \), where \( P_1 \) denotes the projector onto the subspace spanned by \( \Omega \), we get

\[
q_{\tilde{H}^V_2(m)} \geq (H^V_2(m)) + m - mI \otimes P_1.
\]

In addition, we define the unitary operator \( U_P \) from \( F_s \) into \( F_s \otimes F_s \) by

\[
U_P a^*(h) U_P := a^*(j_1, ph) \otimes I + I \otimes a^*(j_2, ph),
\]

for all \( h \in L^2(\mathbb{R}^3; \mathbb{C}^2) \), and where \( j_1, p, j_2, p \in C_0^\infty(\mathbb{R}^3) \) are such that

\[
\begin{cases}
  * j_1 = 1 \text{ in the ball } B(0, 1), \\
  * j_1 = 0 \text{ outside the ball } B(0, 2), \\
  * 0 \leq j_1 \leq 1, \\
  * j_2^2 + j_2^2 = 1,
\end{cases}
\]

and \( j_i, p(k) := j_i(k/p) \) for \( i = 1, 2 \).

Then, following [GLL, lemma A.1], we can show that

\[
q_{H^V_2(m)}(\phi_1, T \Psi^j, \phi_1, T \Psi^j) = q_{H^V_2(m)}(U_P \phi_1, T \Psi^j, U_P \phi_1, T \Psi^j) + \nu(m, P, T)
\]

where \( \nu(m, P, T) \) is such that for all fixed \( m, T, \nu(m, P, T) \rightarrow 0 \).

Thus (64) leads to

\[
q_{H^V_2(m)}(\phi_1, T \Psi^j, \phi_1, T \Psi^j) \geq [E(H^V_2(m)) + m |(\phi_1, T \Psi^j, \phi_1, T \Psi^j) + \nu(m, P, T) - m(U_P \phi_1, T \Psi^j, I \otimes P_2) U_P \phi_1, T \Psi^j)]
= [E(H^V_2(m)) + m |(\phi_1, T \Psi^j, \phi_1, T \Psi^j) + \nu(m, P, T) - \nu'(m, P, T, j)]
\]

with \( \nu'(m, P, T, j) := m(U_P \phi_1, T \Psi^j, I \otimes P_2 U_P \phi_1, T \Psi^j) \).

Lemma A.3 in [GLL] tells us that for all fixed \( m, P, T, \lim \inf_{j \rightarrow \infty} \nu'(m, P, T, j) = 0 \). The point to get this result is that \( \phi_1, T \) is compactly supported, so that the operator

\[
\phi_1, T \Gamma(j_1) \left[ 1 + \sum_{j=1,2} p_j^2 + H_f(m) \right]^{-1/2}
\]

25
is compact, where $\Gamma (j_1)$ is defined by $\Gamma (j_1) a^*(f_1) \ldots a^*(f_n) \Omega \equiv a^*(j_1 f_1) \ldots a^*(j_n f_n) \Omega$.

Next, let us estimate $q_{H_V^V(m)} (\phi_{2,T} \Psi^j, \phi_{2,T} \Psi^j)$. We have

$$ q_{H_V^V(m)} (\phi_{2,T} \Psi^j, \phi_{2,T} \Psi^j) = q_{H_0^V(m)} (\phi_{2,T} \Psi^j, \phi_{2,T} \Psi^j) - ((-V)^{1/2} \phi_{2,T} \Psi^j, (-V)^{1/2} \phi_{2,T} \Psi^j). $$

Since $\phi_{2,T}$ is supported in $\{ X \in \mathbb{R}^6, |r| \geq T \}$, we get

$$ q_{H_V^V(m)} (\phi_{2,T} \Psi^j, \phi_{2,T} \Psi^j) \geq \left[ E(H_0^V(m)) - \frac{C}{T} \right] (\phi_{2,T} \Psi^j, \phi_{2,T} \Psi^j). \quad (67) $$

Finally, let us estimate $q_{H_V^V(m)} (\phi_{3,T} \Psi^j, \phi_{3,T} \Psi^j)$. We have

$$ q_{H_V^V(m)} (\phi_{3,T} \Psi^j, \phi_{3,T} \Psi^j) = q_{H_0^V(m)} (\phi_{3,T} \Psi^j, \phi_{3,T} \Psi^j) + ((U^+)^{1/2} \phi_{3,T} \Psi^j, (U^+)^{1/2} \phi_{3,T} \Psi^j) - ((U^-)^{1/2} \phi_{3,T} \Psi^j, (U^-)^{1/2} \phi_{3,T} \Psi^j). $$

But $\phi_{3,T}$ is supported in $\{ X \in \mathbb{R}^6, |R| \geq T \}$ and we know by $(H_0)$ that $U^-$ is compactly supported. So $(U^-)^{1/2} \phi_{3,T} = 0$ for any $T$ large enough. Therefore

$$ q_{H_V^V(m)} (\phi_{3,T} \Psi^j, \phi_{3,T} \Psi^j) \geq E(H_0^V(m)) (\phi_{3,T} \Psi^j, \phi_{3,T} \Psi^j), \quad (68) $$

for any $T$ large enough.

Then, $(62)$ with the inequalities $(63), (66), (67), (68)$ leads to

$$ q_{H_V^V(m)} (\Psi^j, \Psi^j) \geq \min \left[ E(H_0^V(m)) + m, E(H_0^V(m)), E(H_0^V(m)) \right] + \nu (m, P, T) + \nu' (m, P, T, j) - \frac{C}{T} = \frac{C_{\text{ste}}}{T^2}, $$

for any $T$ large enough.

Let $\varepsilon > 0$ and pick $T_0$ large enough such that $-C/T_0 - C_{\text{ste}}/T_0^2 \geq -\varepsilon$. Next, pick $P_0$ such that $|\nu (m, P_0, T_0)| \leq \varepsilon$. Then $\liminf_{j \to \infty} (\nu' (m, P_0, T_0, j)) = 0$ for any $m$ small enough, which yields

$$ \liminf_{j \to \infty} \left( q_{H_V^V(m)} (\Psi^j, \Psi^j) \right) \geq \min \left[ E(H_0^V(m)) + m, E(H_0^V(m)), E(H_0^V(m)) \right] - 2\varepsilon, $$

for all $\varepsilon > 0$ and any $m$ small enough. Thus,

$$ \liminf_{j \to \infty} \left( q_{H_V^V(m)} (\Psi^j, \Psi^j) \right) \geq \min \left[ E(H_0^V(m)) + m, E(H_0^V(m)), E(H_0^V(m)) \right] \geq E(H_0^V(m)), $$

for any $m$ small enough (see the remark 3.1 above).

Thus the proof is complete. \(\square\)
4.2 Exponential decay of the ground state $\Phi_m$

In order to prove the exponential localization of $\Phi_m$, we follow [GLL, lemma 6.2], with some modifications. More precisely, we would like to show that $\|\exp(\beta|X|)\Phi_m\|$ (where $\beta$ is a suitable constant) is bounded by a constant which does not depend on $m$. In [GLL], the bound depended on $m$. Here, the proof is simpler, and we do not need to follow [G].

**Lemma 4.1** Let $\Phi_m$ be a normalized ground state for $H_V^Y(m)$.

*Then for all $\beta > 0$ such that $0 < \beta^2 < \min(E(H_V^Y) - E(H_0^V), E(H_0^V) - E(H_V^Y))$, we have*

$$\left\|e^{\beta|X|}\Phi_m\right\|_H^2 \leq C_0,$$

*for any $m$ small enough. Here, $C_0$ is a positive constant which does not depend on $m$.*

**Proof** For $i = 1, 2, 3$, $\phi_{i,T}$ denotes the function defined in the previous subsection. Moreover, we set

$$\overline{\phi}_{1,T} = \sqrt{\phi^2_{1,T} + \phi^2_{2,T}},$$

*that is $\overline{\phi}^2_{1,T} = 1 - \phi^2_{1,T}$. We have*

$$\left\|e^{\beta|X|}\Phi_m\right\|^2_H = \left\|e^{\beta|X|}\Phi_m\right\|^2 + \left\|\overline{\phi}_{1,T}e^{\beta|X|}\Phi_m\right\|^2,$$

*and since $\phi_{1,T}$ is compactly supported, the first of this two terms is bounded by a positive constant $C_1$ that does not depend on $m$. We set $G_T := \overline{\phi}_{1,T}\exp(f_\varepsilon)$ where $f_\varepsilon$ is defined for all $\varepsilon > 0$ by*

$$f_\varepsilon(X) := \frac{\beta|X|}{1 + \varepsilon|X|}.$$  

*Note that $f_\varepsilon$ and $|\nabla f_\varepsilon|$ are bounded functions. Thus, $G_T\Phi_m \in Q(H_V^Y(m))$, and using the fact that $\Phi_m$ is a ground state for $H_V^Y(m)$, we can show*

$$q_{H_V^Y(m)}(G_T\Phi_m, G_T\Phi_m) - E(H_V^Y(m))\|G_T\Phi_m\|^2 = (\Phi_m, |\nabla G_T|^2\Phi_m).$$

*But we can compute*

$$|\nabla G_T|^2 = |\nabla \overline{\phi}_{1,T}|^2e^{2f_\varepsilon} + 2(\nabla \overline{\phi}_{1,T}, \nabla f_\varepsilon)e^{f_\varepsilon}G_T + |\nabla f_\varepsilon|^2G_T^2.$$  

*Therefore*

$$q_{H_V^Y(m)}(G_T\Phi_m, G_T\Phi_m) - E(H_V^Y(m))\|G_T\Phi_m\|^2 = (\Phi_m, |\nabla \overline{\phi}_{1,T}|^2e^{2f_\varepsilon} + 2(\nabla \overline{\phi}_{1,T}, \nabla f_\varepsilon)e^{f_\varepsilon}G_T) \Phi_m) \leq C_2,$$

*where $C_2$ is a positive constant which depends on $T$ but not on $m$ or $\varepsilon$. Here, we used the fact that $\nabla \overline{\phi}_{1,T}$ is compactly supported.*

*In addition, we note that $\phi_{1,T/2,\overline{\phi}_{1,T}} = 0$. Thus*

$$q_{H_V^Y(m)}(G_T\Phi_m, G_T\Phi_m) = \sum_{i=2,3} q_{H_V^Y(m)}(G_T\Phi_m, \phi_{i,T/2}^2G_T\Phi_m)$$

$$= \sum_{i=2,3} q_{H_V^Y(m)}(\phi_{i,T/2}G_T\Phi_m, \phi_{i,T/2}G_T\Phi_m) - \sum_{i=2,3} (G_T\Phi_m, |\nabla \phi_{i,T/2}|^2G_T\Phi_m).$$

27
Thus, remark 3 for any $T$ large enough. This leads to

$$q_{H_Y}(m)G_T\Phi_m \geq \min \left[ E(H_Y^0(m)), E(H_Y^0(m)) \right] \|G_T\Phi_m\|^2 - \left( \frac{2C}{T} + \text{Cste} \right) \|G_T\Phi_m\|^2,$$

for any $T$ large enough. Since $|\nabla f_k| \leq \beta$, we get

$$q_{H_Y}(m)G_T\Phi_m - E(H_Y^0(m))\|G_T\Phi_m\|^2 - (G_T\Phi_m, |\nabla f_k|^2 G_T\Phi_m)$$

$$\geq \frac{1}{2} \left[ \min \left[ E(H_Y^0), E(H_Y^0), E(H_Y^0) \right] - \beta^2 \right] \|G_T\Phi_m\|^2 - \left( \frac{2C}{T} + \text{Cste} \right) \|G_T\Phi_m\|^2,$$

for any $m$ small enough. Therefore, we can choose $T_0$ such that

$$q_{H_Y}(m)G_{T_0}\Phi_{m,T_0} - E(H_Y^0(m))\|G_{T_0}\Phi_{m,T_0}\|^2 - (G_{T_0}\Phi_{m,T_0}, |\nabla f_k|^2 G_{T_0}\Phi_{m,T_0})$$

$$\geq \frac{1}{4} \left[ \min \left[ E(H_Y^0), E(H_Y^0), E(H_Y^0) \right] - \beta^2 \right] \|G_{T_0}\Phi_{m,T_0}\|^2,$$

(73)

for any $m$ small enough. (72) and (73) yield

$$\|G_{T_0}\Phi_{m,T_0}\|^2 \leq \frac{4C_2}{\min \left[ E(H_Y^0), E(H_Y^0), E(H_Y^0) \right] - \beta^2} := C_3,$$

for any $m$ small enough and any $\varepsilon > 0$. Thus, as $\varepsilon \to 0$, we get

$$\left| \bar{\phi}_{1,T_0}\tilde{e}^{\beta|X|}\Phi_{m,T_0} \right|^2 \leq C_3,$$

for any $m$ small enough. So the proof is complete with $C_0 := C_1 + C_3$. □

### 4.3 Convergence of the ground state $\Phi_m$ when $m \to 0$

The end of the proof of the existence of a ground state for $H_Y^0$ follows step by step the one in [GLL]. Namely, it is shown that $\|\tilde{a}_k\hat{\alpha}(k)\Phi_m\|$ and $\|\nabla_k \tilde{a}_k\hat{\alpha}(k)\Phi_m\|$ are bounded for almost every $k$, with bounds that do not depend on $m$. Next the Rellich-Kondrachov theorem leads to the conclusion. We only give the results.
Theorem 4.2 Let \( \Phi_m \) be a normalized ground state for \( H_U^Y(m) \), where \( m > 0 \) is small. Then, for almost every \( k \in \mathbb{R}^3 \), we have
\[
\| \hat{\alpha}_\Lambda(k)\Phi_m \| \leq C_\Lambda (|q_1| + |q_2|) \frac{\tilde{\chi}_\Lambda(k)}{|k|^{1/2}} \|X|\Phi_m\|. \tag{74}
\]
Moreover, for almost every \( k \in \mathbb{R}^3 \) such that \(|k| < \Lambda/2 \) and \((k_1, k_2) \neq (0, 0)\), we have
\[
\| \nabla_k \hat{\alpha}_\Lambda(k)\Phi_m \| \leq C'_\Lambda (|q_1| + |q_2|) \frac{1}{|k|^{1/2} \sqrt{k_1^2 + k_2^2}} \|X|\Phi_m\|. \tag{75}
\]
Here \( C_\Lambda \) and \( C'_\Lambda \) are constants that depend on \( \Lambda \), \( m_1 \), \( m_2 \), but not on \( m \).

Remark 4.1

1. Note that \( \Phi_m \in Q(N) \) by (40). Then (74) means
\[
q_N(\Phi_m, \Phi_m) \leq C^2_\Lambda (|q_1| + |q_2|)^2 \int_{\mathbb{R}^3} \frac{\tilde{\chi}_\Lambda(k)}{|k|} dk \|X|\Phi_m\|^2. \tag{76}
\]
The meaning of (75) is given in the appendix B of [GLL].

2. A key step to obtain (74) and (75) is to use the following gauge transformation: the unitary operator \( T \) is defined by
\[
T = \int_{\mathbb{R}^3} (X) dX \quad \text{with} \quad T(X) = e^{-i \sum_{j=1.2} q_j x_j - A(0)}. \tag{77}
\]
Then we have \( \tilde{J}_\Lambda(k, X) := T(X)\tilde{\alpha}_\Lambda(k)^* T(X) = \tilde{\alpha}_\Lambda(k) - i w_\Lambda(k, X) \), with
\[
w_\Lambda(k, X) = \frac{1}{2\pi} \frac{\tilde{\chi}_\Lambda(k)}{|k|^{1/2}} \varepsilon_\Lambda(k) \sum_{j=1.2} q_j x_j. \tag{78}
\]
Hence the transformed Hamiltonian is
\[
\tilde{H}_U^Y(m) := T H_U^Y(m) T^* = \sum_{j=1.2} \frac{1}{2 m_j} (p_j - q_j \tilde{A}_j)^2 + \tilde{H}_f(m) + U + V, \tag{79}
\]
with \( \tilde{A}_j = \int_{\mathbb{R}^3} \tilde{A}_j(X) dX \), \( \tilde{H}_f(m) = \int_{\mathbb{R}^3} \tilde{H}_f(m)(X) dX \), and
\[
\tilde{A}_j(X) = A(x_j) - A(0), \quad \tilde{H}_f(m)(X) = \sum_{\lambda=1.2} \int_{\mathbb{R}^3} \omega_m(k) \tilde{\alpha}_\Lambda(k, X) \tilde{\alpha}_\Lambda(k, X) dk. \tag{80}
\]

3. Theorem 4.2 together with lemma 4.1 show that \( \| \hat{\alpha}_\Lambda(k) \Phi_m \| \) and \( \| \nabla_k \hat{\alpha}_\Lambda(k) \Phi_m \| \) are uniformly bounded for small \( m \).

Now let \( (m_j) \) be a sequence that decays to 0 and such that (74) and (75) are satisfied for all \( j \). We can suppose that \( \Phi_{m_j} \) converges weakly to a limit \( \Phi \) when \( j \) goes to \( \infty \). Let us show that \( \Phi \in D(H_U^Y) \).

Since, for all \( j \), \( Q(H_U^Y(m_j)) \subset Q(H_U^Y) \) by (40), we can write
\[
\left\| \left[ H_U^Y - E(H_U^Y) \right]^{1/2} \Phi_{m_j} \right\|^2 = q_{H_U^Y}(\Phi_{m_j}, \Phi_{m_j}) - E(H_U^Y) \\
\leq q_{H_U^Y}(\phi_{m_j}, \phi_{m_j}) - E(H_U^Y) = E(H_U^Y(m_j)) - E(H_U^Y) \to 0 \quad j \to \infty.
\]
Thus, for all $\psi \in Q(H^V_U)$, we have

$$\left\langle \left( H^V_U - E(H^V_U) \right)^{1/2} \psi, \Phi \right\rangle = \lim_{j \to \infty} \left\langle \left( H^V_U - E(H^V_U) \right)^{1/2} \psi, \Phi_m \right\rangle$$

$$= \lim_{j \to \infty} \left( \psi, \left( H^V_U - E(H^V_U) \right)^{1/2} \Phi_m \right) = 0.$$ 

Therefore, $\Phi \in Q(H^V_U)$ and $\left( H^V_U - E(H^V_U) \right)^{1/2} \Phi = 0$. This yields

$$\Phi \in D(H^V_U) \quad \text{and} \quad H^V_U \Phi = E(H^V_U) \Phi.$$  \hspace{1cm} (81)

Then, in the same way as in theorem 7.1 of [GLL], (81), lemma 4.1 and theorem 4.2 lead to

**Theorem 4.3** $\Phi_m$ converges strongly to $\Phi$, so that $\|\Phi\| = 1$ and $\Phi$ is a ground state for $H^V_U$.

**Remark 4.2** With the help of the functional integral representation of remark 2.1, we can prove that the ground state of $H^V_U$ is non-degenerate. Indeed, it is shown in [H2], that $\nu^{-1} e^{-iH^V_U}$ is positivity improving as an operator acting on $L^2(\mathbb{R}^6 \times Q)$, where $L^2(Q)$ denotes a Schrödinger representation of $F$, and where $\nu$ is a unitary operator from $L^2(Q)$ to $F$.
