

Geometric Analysis of Metropolis Algorithm on Bounded Domain

L. Michel

(joint work with P. Diaconis and G. Lebeau)

Laboratoire J.-A. Dieudonné
Université de Nice

Let $\mu = \rho(x)dx$ be a probability measure on $[a, b]$ and let f be a regular function on $[a, b]$. We want to compute numerically the quantity $I = \frac{1}{b-a} \int_a^b f(x)d\mu(x)$.

- Standard "deterministic" method consist to divide $[a, b]$ into N interval and to approximate I by $\sum_{k=1}^N A_k$ where A_k is the area corresponding to the k th interval.
- Probabilist approach: let $(x_n)_{n \in \mathbb{N}}$ be a sequence of numbers in $[a, b]$ such that x_n is chosen at random with respect to μ . Then, the quantity $\frac{1}{N} \sum_{n=1}^N f(x_n)$ provides a good approximation of I .
- A priori, "choose a point at random with respect to μ " is not a simpler problem than "compute I ".
The Metropolis Algorithm provides an efficient procedure to sample from μ .

The problem of hard spheres

Consider a fixed box in \mathbb{R}^d , $B =]-1, 1[^d$. We consider the problem of placement of N balls of radius $\epsilon > 0$ with centers in B under the condition that **the balls do not overlap**. We denote $\mathcal{O}_{N,\epsilon} \subset B^N$ the set of all possible configurations. We endow $\mathcal{O}_{N,\epsilon}$ with the Lebesgue measure dL .

Problem:

Build a sample of points $X^1, \dots, X^r \in \mathcal{O}_{N,\epsilon}$ distributed uniformly with respect to dL .

- This problem occurs in statistical physics in phase transition studies.
- It can be formulated in a more abstract setting.

Metropolis and al (50's) proposed the following algorithm to solve this problem. Let $h > 0$ being fixed and $X^0 \in \mathcal{O}_{N,\epsilon}$.

- Starting from $X^0 = (x_1^0, \dots, x_N^0)$, move one of the ball say x_k^0 uniformly at random in the ball $B(x_k^0, h)$, it results in a new position x_k^1 . Denote $X^1 = (x_1^0, \dots, x_k^1, \dots, x_N^0)$ the new configuration. If $X^1 \in \mathcal{O}_{N,\epsilon}$, keep X^1 .
- If $X^1 \notin \mathcal{O}_{N,\epsilon}$, throw away X^1 and restart the procedure from X^0 .
- Once, X^1 is constructed, define X^2 by the same procedure starting from X^1 , etc.

As r goes to infinity, the distribution of X^0, \dots, X^r in $\mathcal{O}_{N,\epsilon}$ is close to the uniform distribution.

Abstract probabilistic setting

Let (X, d) be a metric space and \mathcal{B} the Borel σ -algebra on X . Let $K(x, dy)$ be a Markov kernel on X , i.e.

- for all $x \in X$, $K(x, dy)$ is a probability measure on (X, \mathcal{B}) .
- for all $B \in \mathcal{B}$, $x \mapsto K(x, B)$ is continuous (to simplify).

For $n \in \mathbb{N}^*$ we define the iterated kernel $K^n(x, dy)$ by

$$K^{m+n}(x, B) = \int K^m(y, B)K^n(x, dy), \forall B \in \mathcal{B}$$

The kernel K induces an operator on continuous functions by

$$Kf(x) = \int_X f(y)K(x, dy)$$

and its transpose acts on Borel measure on X .

Definition

A stationary distribution is a probability measure $\pi(dx)$ on X such that ${}^tK(\pi) = \pi$. In other words:

$$\forall B \in \mathcal{B}, \pi(B) = \int K(x, B)\pi(dx)$$

example

Suppose that X is a finite space and let $n = \#X$. Then a Markov kernel is a matrix $(K(x, y))_{1 \leq x, y \leq n}$ with non-negative coefficients and such that for any $x \in X$, $\sum_{y \in X} K(x, y) = 1$. Hence, a stationary distribution is an eigenvector of tK associated to the eigenvalue 1 and with non-negative coordinates.

Theorem

Suppose that $K(x, dy)$ is a *strictly positive, regular* Markov kernel and that $\pi(dx)$ is stationary for K . Then,

$$\forall x \in X, \forall B \in \mathcal{B}, \lim_{n \rightarrow \infty} K^n(x, B) = \pi(B)$$

A Markov kernel is strictly positive if $K(x, A) > 0$ for any open subset A . We do not define the notion of regular Markov kernel. Think it as a density $k(x, y)dy$ on an open subset of \mathbb{R}^d , with k continuous w.r.t. (x, y) (enough to apply Ascoli's theorem).

Question

What can we say about the speed of convergence?

Given a **probability distribution π on X** we may be interested in sampling π . From the preceding theorem, it is clear that **if $K(x, dy)$ is a Markov kernel for which π is stationary**, we can build a sample by the following process:

- Start from $x^0 \in X$ and build $x^1 \in X$ at random with the probability $K(x^0, dy)$.
- Knowing $x^0, \dots, x^n \in X$ build x^{n+1} at random with the probability $K(x^n, dy)$.

Since $K^n(x, dy)$ converges to π , the distribution of the point x^0, \dots, x^n “looks like” it was chosen according to π .

Question

Given a probability π , how can we construct a Markov kernel $K(x, dy)$ such that π is stationary for K ?

The Metropolis Algorithm on Lipschitz domain

Our framework is the following:

- Ω denotes a bounded connected open subset of \mathbb{R}^d s.t. $\partial\Omega$ has Lipschitz regularity.
- ρ is a measurable function on $\overline{\Omega}$ such that
 - * there exists $m, M > 0$, s.t. $m \leq \rho(x) \leq M$, $\forall x \in \Omega$.
 - * $\int_{\Omega} \rho(x) dx = 1$
- B_1 denotes the unit ball in \mathbb{R}^d and $|B_1|$ its volume.

We are willing to define a Markov kernel which permit to sample from $\rho(x) dx$.

Introduce the following kernel on Ω :

$$K_{h,\rho}(x, y) = \frac{1}{h^d |B_1|} 1_{|x-y| < h} \min\left(\frac{\rho(y)}{\rho(x)}, 1\right)$$

The Metropolis kernel is given by

$$T_{h,\rho}(x, dy) = m_{h,\rho}(x)\delta_x + K_{h,\rho}(x, y)dy.$$

with

$$m_{h,\rho}(x) = 1 - \int_{\Omega} K_{h,\rho}(x, y)dy$$

The Metropolis operator associated to this kernel is

$$T_{h,\rho}u(x) = m_{h,\rho}(x)u(x) + \int_{\Omega} u(y)K_{h,\rho}(x, y)dy$$

Basic properties

- The Metropolis kernel $T_{h,\rho}(x, dy)$ is a Markov kernel ($T_{h,\rho}(1) = 1$).
- The operator $T_{h,\rho}$ is self-adjoint on $L^2(\Omega, \rho(x)dx)$ and $\|T_{h,\rho}\|_{L^2 \rightarrow L^2} = 1$.
- The probability measure $\rho(x)dx$ is stationary for $T_{h,\rho}$.
- $\text{Spec}(T_h)$ is discrete near 1 (use [this](#)).

Definition

We define the spectral gap of the Metropolis operator $T_{h,\rho}$ as $g(h, \rho) = \text{dist}(1, \text{spect}(T_h) \setminus \{1\})$. This is the largest constant such that

$$\|u\|_{L^2(\rho)}^2 - \langle u, 1 \rangle_{L^2(\rho)}^2 \leq \frac{1}{g(h, \rho)} \langle u - T_{h,\rho}u, u \rangle_{L^2(\rho)}$$

Theorem 1

Let Ω be an open, connected, bounded, Lipschitz subset of \mathbb{R}^d . There exists $h_0 > 0$, $\delta_0 \in]0, 1/2[$ and constants $C_i > 0$ such that for $h \in]0, h_0]$, the following holds true:

- $\text{Spec}(T_{h,\rho}) \subset [-1 + \delta_0, 1]$
- 1 is a simple eigenvalue of $T_{h,\rho}$
- The spectral gap $g(h, \rho)$ satisfies

$$C_2 h^2 \leq g(h, \rho) \leq C_3 h^2$$

- $\forall \lambda \in [0, \delta_0]$,

$$\#\left(\text{Spect}(T_{h,\rho}) \cap [1 - \lambda, 1]\right) \leq C(1 + \lambda h^{-2})^{d/2}$$

Total variation estimate

The **total variation distance** between two probability measures μ, ν is defined by

$$\|\mu - \nu\|_{TV} = \sup_{A \text{ measurable}} |\mu(A) - \nu(A)| = \frac{1}{2} \sup_{f \in L^\infty, |f| \leq 1} \left| \int f d\mu - \int f d\nu \right|$$

Theorem 2

Under the same assumption as above, the following estimate holds true for all $n \in \mathbb{N}$:

$$C_4 e^{-ng(h,\rho)} \leq \sup_{x \in \Omega} \|T_{h,\rho}^n(x, dy) - \rho(y) dy\|_{TV} \leq C_5 e^{-ng(h,\rho)}.$$

Variational approach

Since, $m \leq \rho(x) \leq M$ on Ω , we can easily suppose that $\rho = 1$ (and we denote T_h instead of $T_{h,\rho}$). The spectral gap is the largest constant such that

$$\|u\|_{L^2}^2 - \langle u, 1 \rangle_{L^2}^2 \leq \frac{1}{g(h, \rho)} \langle u - T_h u, u \rangle_{L^2}$$

A standard computation shows that

$$\|u\|_{L^2}^2 - \langle u, 1 \rangle_{L^2}^2 = \frac{1}{2} \int_{\Omega \times \Omega} |u(x) - u(y)|^2 dx dy := \text{Var}(u)$$

$$\langle u - T_h u, u \rangle_{L^2} = \frac{h^{-d}}{2} \int_{\Omega \times \Omega} 1_{|x-y| < h} |u(x) - u(y)|^2 dx dy := \mathcal{E}_h(u).$$

Hence, the spectral gap is the largest constant s.t.

$$\text{Var}(u) \leq \frac{1}{g} \mathcal{E}_h(u)$$

The following properties are easy to prove:

- 1 is a simple eigenvalue (use [this](#))
- $g(h, \rho) \leq Ch^2$ (take $u \in C_0^\infty(\Omega)$ such that $\int_\Omega u(x)dx = 0$, $\|u\|_{L^2} = 1$, make a Taylor expansion and use again [this](#))

Lower bound for the spectral gap

Let us show the lower bound on the spectral gap when Ω is convex. For any $u \in L^2(\Omega)$, we have

$$\int_{\Omega \times \Omega} |u(x) - u(y)|^2 dx dy \leq Ch^{-1} \sum_{k=0}^{K(h)-1} \int_{\Omega \times \Omega} |u(x + k\hbar(y-x)) - u(x + (k+1)\hbar(y-x))|^2 dx dy,$$

where $K(h)$ is the greatest integer $\leq h^{-1}$ and $K(h)\hbar = 1$.

With the new variables $x' = x + k\bar{h}(y - x)$,
 $y' = x + (k + 1)\bar{h}(y - x)$, one has $dx'dy' = \bar{h}^d dx dy$ and we get

$$\int_{\Omega \times \Omega} |u(x) - u(y)|^2 dx dy \leq$$

$$Ch^{-d-1} K(h) \int_{\Omega \times \Omega} \mathbf{1}_{|x'-y'| < \bar{h} \text{diam}(\Omega)} |u(x') - u(y')|^2 dx' dy',$$

This yields to

$$\text{Var}(u) \leq C'h^{-2} \mathcal{E}_h(u)$$

and proves the lower bound.

Proof of total variation estimates

Let Π_0 be the orthogonal projector in $L^2(\Omega)$ on the space of constant functions

$$\Pi_0(u)(x) = 1_{\Omega}(x) \int_{\Omega} u(y) dy. \quad (1)$$

Then, **by definition**

$$2 \sup_{x_0 \in \Omega} \|T_h^n(x_0, dy) - dy\|_{TV} = \|T_h^n - \Pi_0\|_{L^\infty \rightarrow L^\infty}. \quad (2)$$

Thus, we have to prove that for $h > 0$ small and any n , one has

$$\|T_h^n - \Pi_0\|_{L^\infty \rightarrow L^\infty} \leq C_0 e^{-ng(h, \rho)}. \quad (3)$$

Since $g(h, \rho) = O(h^2)$, we can suppose that $nh^2 \gg 1$.

Denote $\lambda_{j,h}$ the eigenvalues of T_h and Π_j the associated spectral projector. We fix $\alpha > 0$ small and use the spectral decomposition $T_h - \Pi_0 = T_{h,1} + T_{h,2}$ with

$$T_{h,1} = \sum_{1-h^{2-\alpha} < \lambda_{j,h} < 1} \lambda_{j,h} \Pi_j$$

and $T_{h,2}$ spectrally localized in $[-1 + \delta_0, 1 - h^{2-\alpha}]$. It is easy to see that

$$\|T_h^n - \Pi_0\|_{L^2 \rightarrow L^2} \leq C e^{-ng(h,\rho)}.$$

Since, we deal with $L^\infty \rightarrow L^\infty$ norm, we need:

- to control $\|\Pi_j\|_{L^2 \rightarrow L^\infty}$
- a bound on the number of eigenvalues in any interval $[\alpha_h, 1]$ with $1 - \delta_0 < \alpha_h < 1 - Ch^2$.

For this purpose, we compare our operator with a more simple one.

Comparison with the random walk on the torus

Since Ω is bounded, it is contained in a large box $] - A, A[^d$. We denote $\Pi = (\mathbb{R}/2A\mathbb{Z})^d$. Since Ω is Lipschitz, using local coordinates, we can define an extension map

$$P : L^2(\Omega) \rightarrow L^2(\Pi)$$

which is also bounded from $H^1(\Omega)$ into $H^1(\Pi)$.

Any function $v \in L^2(\Pi)$ can be extended in Fourier series $v(x) = \sum_{k \in \mathbb{Z}^d} c_k(v) e^{2ik\pi x/A}$. The L^2 and H^1 norm on Π can be expressed as follows

- $\|v\|_{L^2(\Pi)}^2 = (2A)^d \sum_k |c_k|^2$.
- $\|v\|_{H^1(\Pi)}^2 = (2A)^d \sum_k \left(1 + \frac{4\pi^2 k^2}{A^2}\right) |c_k|^2$.

Recall that for $u \in L^2(\Omega)$,

$$\mathcal{E}_h(u) = \langle u - T_h u, u \rangle_{L^2(\Omega)} = \frac{h^{-d}}{2} \int_{\Omega \times \Omega} \mathbf{1}_{|x-y|<h} |u(x) - u(y)|^2 dx dy.$$

For $v \in L^2(\Pi)$, we define

$$\tilde{\mathcal{E}}_h(v) = \langle u - \tilde{T}_h u, u \rangle_{L^2(\Pi)} = \frac{h^{-d}}{2} \int_{\Pi \times \Pi} \mathbf{1}_{|x-y|<h} |v(x) - v(y)|^2 dx dy.$$

where \tilde{T}_h is the metropolis operator on the torus.

Remark

A simple calculus using the Fourier expansion, shows that $\tilde{T}_h = \Gamma(-h^2 \Delta)$ where Γ is a smooth function decreasing to 0 at infinity.

Lemma 1

There exist $C_0, C_1, h_0 > 0$ such that the following holds true for any $h \in]0, h_0]$ and any $u \in L^2(\Omega)$.

$$\mathcal{E}_h(u)/C_0 \leq \tilde{\mathcal{E}}_h(P(u)) \leq C_0 (\mathcal{E}_h(u) + h^2 \|u\|_{L^2}^2). \quad (4)$$

As a by-product, any $u \in L^2(\Omega)$ such that

$$\|u\|_{L^2(\rho)}^2 + h^{-2} \langle (1 - T_h)u, u \rangle_{L^2(\rho)} \leq 1$$

admits a decomposition $u = u_L + u_H$ with $u_L \in H^1(\Omega)$, $\|u_L\|_{H^1} \leq C_1$, and $\|u_H\|_{L^2} \leq C_1 h$.

Proof.

- The first inequality is trivial. The second one is obtained by working in local coordinates for which the boundary is an half-space.
- We observe that (thanks to Parseval identity)

$$\tilde{\mathcal{E}}_h(v) = \frac{(2A)^d}{2} \sum_k |c_k|^2 \theta(hk/A),$$

$$\theta(\xi) = \int_{|z| \leq 1} |e^{2i\pi\xi z} - 1|^2 dz.$$

The by-product is obtained by projecting the extension $v = P(u)$ on low frequencies $h|k| \leq \delta$ and high frequencies $h|k| > \delta$ for some fixed $\delta > 0$. Hence, it suffices to use the fact that **the function θ is quadratic near 0 and has a positive lower bound for $|\xi| \geq \delta$.**

Control of small eigenvalues

Using the preceding Lemma, we show that there exists $\delta_0 > 0$ s.t.

- for any $0 \leq \lambda \leq \delta_0/h^2$,

$$\#(\text{Spec}(T_h) \cap [1 - h^2\lambda, 1]) \leq C(1 + \lambda)^{d/2}$$

- any eigenfunction $T_h(u) = \lambda u$ with $\lambda \in [1 - \delta_0, 1]$ satisfies the bound

$$\|u\|_{L^\infty} \leq C_2 h^{-d/2} \|u\|_{L^2}.$$

Using these estimates we get easily:

$$\|T_{2,h}^n\|_{L^\infty \rightarrow L^\infty} \leq Ch^{-3d/2} e^{-nh^{2-\alpha}} \ll e^{-ng(h,\rho)}$$

since $g(h, \rho) \sim h^2$.

Nash inequality

Let $E_\alpha = \text{span}(e_{j,h}, 1 - h^{2-\alpha} < \lambda_{j,h} < 1)$. We have the following **Nash inequality**:

Lemma 2

There exists $C, D, \alpha > 0$, s.t. any function $u \in E_\alpha$ satisfies:

$$\|u\|_{L^2}^{2+1/D} \leq Ch^{-2} (\|u\|_{L^2}^2 - \|T_h u\|_{L^2}^2 + h^2 \|u\|_{L^2}^2) \|u\|_{L^1}^{1/D}.$$

Proof.

- Use [Lemma 1](#) to show that there exists $p > 2$ such that any function $u \in E_\alpha$ satisfies

$$\|u\|_{L^p}^2 \leq Ch^{-2} (\|u\|_{L^2}^2 - \|T_h u\|_{L^2}^2 + h^2 \|u\|_{L^2}^2)$$

- Interpolate between L^p and L^1 to get the L^2 estimate.

Control of $T_{h,1}$

We want to control the norm $\|T_{h,1}^n\|_{L^2 \rightarrow L^\infty} = \|T_{h,1}^n\|_{L^1 \rightarrow L^2}$.

- Take $g \in L^2$ s.t. $\|g\|_{L^1} = 1$ and denote $c_n = \|T_{h,1}^n g\|_{L^2}^2$.
Thanks to the preceding Lemma:

$$c_n^{1+2D} \leq Ch^{-2}(c_n - c_{n+1} + h^2 c_n)$$

Hence, for $0 \leq n \leq h^{-2}$, $c_n \leq (h^{-2}/(1+n))^{2D}$.

- This permit to show that for some large $n \simeq h^{-2}$,

$$\|T_{h,1}^n\|_{L^2 \rightarrow L^\infty} = \|T_{h,1}^n\|_{L^1 \rightarrow L^2} = O(1)$$

Combined with $\|T_h^p\|_{L^2 \rightarrow L^2} \leq Ce^{-pg(h,\rho)}$, this completes the proof.

Case of a smooth density

If the density ρ is smooth on $\bar{\Omega}$ we can give a more precise description of the spectrum of $T_{h,\rho}$. **For simplicity, we assume in this section that $\partial\Omega$ is smooth.** Let us introduce the unbounded operator acting on $L^2(\Omega, \rho(x)dx)$, defined by

$$L_\rho(u) = \frac{-\alpha_d}{2} \left(\Delta u + \frac{\nabla \rho}{\rho} \cdot \nabla u \right)$$
$$D(L_\rho) = \{ u \in H^2(\Omega), \partial_n u|_{\partial\Omega} = 0 \}$$

where

$$\alpha_d = \frac{1}{\text{vol}(B_1)} \int_{B_1} z_1^2 dz = \frac{1}{d+2}$$

- L_ρ is the self-adjoint realization of the Dirichlet form

$$\frac{\alpha_d}{2} \int_{\Omega} |\nabla u(x)|^2 \rho(x) dx. \quad (5)$$

- L_ρ has compact resolvent (thanks to Sobolev embeddings).
- We denote

$$\text{Spec}(L_\rho) = \{\nu_0 = 0 < \nu_1 < \nu_2 < \dots\}$$

and by $m_j = \text{multiplicity}(\nu_j)$. Observe that $m_0 = 1$ since $\text{Ker}(L_\rho)$ is spanned by the constant function equal to 1.

Theorem 3

Let Ω be an open, connected, bounded and smooth subset of \mathbb{R}^d . Assume that the density ρ is smooth on $\overline{\Omega}$, then for any $R > 0$ and $\varepsilon > 0$ such that $\nu_{j+1} - \nu_j > 2\varepsilon$ for $\nu_{j+2} < R$, there exists $h_1 > 0$ such that one has for all $h \in]0, h_1]$,

$$\text{Spec} \left(\frac{1 - T_{h,\rho}}{h^2} \right) \cap]0, R] \subset \cup_{j \geq 1} [\nu_j - \varepsilon, \nu_j + \varepsilon], \quad (6)$$

and the number of eigenvalues of $\frac{1 - T_{h,\rho}}{h^2}$ in the interval $[\nu_j - \varepsilon, \nu_j + \varepsilon]$ is equal to m_j .

A simple quasimode calculus

Assume $\rho = 1$ and $\partial\Omega$ is smooth. Let $\lambda > 0$ and $u \in C^\infty(\bar{\Omega})$ satisfy

$$\left(-\frac{\alpha_d}{2}\Delta - \lambda\right)u = 0 \text{ in } \Omega \quad \text{and} \quad \partial_n u|_{\partial\Omega} = 0.$$

- For $x \in \Omega$ s.t. $\text{dist}(x, \partial\Omega) > h$, Taylor expansion shows that

$$\begin{aligned} T_h u(x) - u(x) &= \int_{|z| < 1, x+hz \in \Omega} (u(x+hz) - u(x)) dz \\ &= h \sum_{j=1}^d \partial_{x_j} u(x) \int_{|z| < 1} z_j dz + \alpha_d h^2 \Delta u(x) + O_{L^\infty}(h^4) \\ &= \frac{\alpha_d}{2} h^2 \Delta u(x) + O_{L^\infty}(h^4) \end{aligned}$$

where the term of order h and h^3 vanish for parity reason.

- For $x \in \Omega$ s.t. $\text{dist}(x, \partial\Omega) < h$, we use local coordinates such that $\Omega = \{(x_1, x') \in \mathbb{R}^d, x_1 > 0\}$. Taylor expansion shows that

$$\begin{aligned} T_h u(x) - u(x) &= \int_{|z| < 1, x_1 + h z_1 > 0} (u(x + h z) - u(x)) dz \\ &= h \sum_{j=1}^d \partial_{x_j} u(x) \int_{|z| < 1, x_1 + h z_1 > 0} z_j dz + O_{L^\infty}(h^2) \end{aligned}$$

- Parity argument \implies term of index $j \geq 2$ vanish.
- $\partial_n u|_{\partial\Omega} = 0$ and $\text{dist}(x, \partial\Omega) < h \implies$ term of index $j = 1$ is $O_{L^\infty}(h^2)$.

Since $\text{meas}(\{\text{dist}(x, \partial\Omega) < h\}) = O(h)$, it follows that

$$1_{\text{dist}(x, \partial\Omega) < h} (T_h u - u) = O_{L^2}(h^{\frac{5}{2}}).$$

Combining the two estimates, we get

$$T_h u - (1 - h^2 \lambda) u = O(h^{\frac{5}{2}}).$$

Application to Random Placement of Non-Overlapping Balls

We consider the initial problem that motivated the works of Metropolis et al. Given an open set $\Omega \subset \mathbb{R}^d$ and $N \in \mathbb{N}$ we consider the set of all possible positions in Ω for N non-overlapping balls of radius $\epsilon > 0$. This can be identified to the possible locations for their centers

$$\mathcal{O}_{N,\epsilon} = \left\{ x = (x_1, \dots, x_N) \in \Omega^N, \forall 1 \leq i < j \leq N, |x_i - x_j| > \epsilon \right\}.$$

The problem we address is to sample from the uniform distribution, according with the following Metropolis algorithm:

Starting from a configuration (X_1, \dots, X_N) we choose a ball at random and move it uniformly at random in a small ball of radius $h > 0$. If it results in an admissible configuration, “we keep” the move. Otherwise we don't move and try again.

This is associated to the following Markov kernel (where $\varphi = 1_{B_{\mathbb{R}^d}(0,1)}$)

$$K_h(x, dy) = \frac{1}{N} \sum_{j=1}^N \delta_{x_1} \otimes \cdots \otimes \delta_{x_{j-1}} \otimes h^{-d} \varphi \left(\frac{x_j - y_j}{h} \right) dy_j \otimes \delta_{x_{j+1}} \otimes \cdots \otimes \delta_{x_N},$$

and the associated Metropolis operator on $L^2(\mathcal{O}_{N,\epsilon})$

$$T_h(u)(x) = m_h(x)u(x) + \int_{\mathcal{O}_{N,\epsilon}} u(y)K_h(x, dy),$$

with

$$m_h(x) = 1 - \int_{\mathcal{O}_{N,\epsilon}} K_h(x, dy).$$

Proposition

There exists $\alpha > 0$ such that for $N\epsilon \leq \alpha$, the set $\mathcal{O}_{N,\epsilon}$ is connected, Lipschitz and quasi-regular.

Proof. The proof is rather technical. The quasiregularity is notion used to replace “smooth” by “Lipschitz”.

To prove the “Lipschitz boundary” use the following caraterisation:

A domain $\mathcal{O} \subset \mathbb{R}^p$ has Lipschitz boundary iff it satisfies the following cone property:

$\forall a \in \partial\mathcal{O}, \exists \delta > 0, \exists \nu_a \in S^{p-1}, \forall b \in B(a, \delta) \cap \partial\mathcal{O}$ we have

$$b + \Gamma_+(\nu_a, \delta) \subset \mathcal{O} \quad \text{and} \quad b + \Gamma_-(\nu_a, \delta) \subset \mathbb{R}^p \setminus \overline{\mathcal{O}}.$$

where for $\nu \in S^p$,

$$\Gamma_+(\nu_a, \delta) = \{\xi \in \mathbb{R}^p, \pm \langle \xi, \nu \rangle > (1 - \delta)|\xi|, |\langle \xi, \nu \rangle| < \delta\}$$

Thanks to the preceding proposition, we can consider the Neumann Laplacian $|\Delta|_N$ on $\mathcal{O}_{N,\epsilon}$ defined by

$$|\Delta|_N = -\frac{\alpha_d}{2N} \Delta,$$

$$D(|\Delta|_N) = \left\{ u \in H^1(\mathcal{O}_{N,\epsilon}), -\Delta u \in L^2(\mathcal{O}_{N,\epsilon}), \partial_n u|_{\partial\mathcal{O}_{N,\epsilon}} = 0 \right\}.$$

We still denote $0 = \nu_0 < \nu_1 < \nu_2 < \dots$ the spectrum of $|\Delta|_N$ and m_j the multiplicity of ν_j .

Theorem (part 1)

Let $N \geq 2$ and $\epsilon > 0$ small be fixed. Let $R > 0$ be given and $\beta > 0$ small. Then, there exists $h_0 > 0$, $\delta_0 \in]0, 1/2[$ and constants $C_i > 0$ such that for any $h \in]0, h_0]$, the following hold true:

- i) The spectrum of T_h is a subset of $[-1 + \delta_0, 1]$, 1 is a simple eigenvalue of T_h , and $\text{Spec}(T_h) \cap [1 - \delta_0, 1]$ is discrete.

Moreover,

$$\text{Spec} \left(\frac{1 - T_h}{h^2} \right) \cap]0, R] \subset \cup_{j \geq 1} [\nu_j - \beta, \nu_j + \beta];$$

$$\# \text{Spec} \left(\frac{1 - T_h}{h^2} \right) \cap [\nu_j - \beta, \nu_j + \beta] = m_j \quad \forall \nu_j \leq R;$$

and for any $0 \leq \lambda \leq \delta_0 h^{-2}$, the number of eigenvalues of T_h in $[1 - h^2 \lambda, 1]$ (with multiplicity) is bounded by $C_1(1 + \lambda)^{dN/2}$.

Theorem (part 2)

ii) The spectral gap $g(h)$ satisfies

$$\lim_{h \rightarrow 0^+} h^{-2} g(h) = \nu_1$$

and the following estimate holds true for all $n \in \mathbb{N}$:

$$\sup_{x \in \mathcal{O}_{N,\epsilon}} \left\| T_h^n(x, dy) - \frac{dy}{\text{vol}(\mathcal{O}_{N,\epsilon})} \right\|_{TV} \leq C_4 e^{-ng(h)}.$$
