Lorentzian geometry

Definition

A \((n \text{ dimensional})\) Lorentzian manifold is a manifold all of whose tangent spaces are endowed with a quadratic form a signature \((n - 1, 1)\).
Lorentzian geometry

**Definition**

A \((n\text{ dimensional})\) Lorentzian manifold is a manifold all of whose tangent spaces are endowed with a quadratic form a signature \((n - 1, 1)\).

On each tangent space, we can see a light cone:

- the vector \(v\) is called timelike, spacelike, lightlike.
A \((n\text{ dimensional})\) Lorentzian manifold is a manifold all of whose tangent spaces are endowed with a quadratic form a signature \((n-1, 1)\).

- On each tangent space, we can see a light cone:

  the vector \(v\) is called \textit{timelike, spacelike, lightlike}.

- A Lorentzian manifold is naturally endowed with a connection, i.e. a way to compute the acceleration, and a volume form (if it is orientable).

### Personal themes of research

#### Space of Lorentzian metrics
- Topology
- Dynamics of the action of the group of diffeomorphisms

#### Geodesically equivalent manifolds
- Projectively equivalent manifolds,
- Affinely equivalent manifolds.

#### Totally geodesic foliations
- **Codimension 1 case:**
  - timelike foliations,
  - foliations of mixed type.
- **Dimension 1 case:**
  - lightlike foliations,
  - foliations by circles.

#### Lorentzian surfaces with a Killing field
- Spacelike Zoll surfaces,
- Conjugate points,
- Extension and classification problems.
A Killing field on a Lorentzian surface \((S, g)\) is a (complete) vector field \(K\) such that \(\mathcal{L}_K g = 0\) i.e. whose flow is a one parameter group of isometries.

The Clifton-Pohl torus

It is the quotient of \(\mathbb{R}^2 \setminus \{(0, 0)\}\) endowed with the metric \(\frac{2dx\,dy}{x^2+y^2}\) by an homothety, usually \((x, y) \mapsto 2(x, y)\).

The radial field of \(\mathbb{R}^2\) induces a periodic Killing field on the torus.
A Killing field on a Lorentzian surface \((S, g)\) is a (complete) vector field \(K\) such that \(\mathcal{L}_K g = 0\) i.e. whose flow is a one parameter group of isometries.

**The Clifton-Pohl torus**

It is the quotient of \(\mathbb{R}^2 \setminus \{(0, 0)\}\) endowed with the metric \(\frac{2\,dx\,dy}{x^2+y^2}\) by an homothety, usually \((x, y) \mapsto 2(x, y)\).

The radial field of \(\mathbb{R}^2\) induces a periodic Killing field on the torus.

A Lorentzian surface with a Killing field carries (at least) 3 natural foliations: the one given by the Killing field and the 2 lightlike one.
A Killing field on a Lorentzian surface \((S, g)\) is a (complete) vector field \(K\) such that \(\mathcal{L}_K g = 0\) i.e. whose flow is a one parameter group of isometries.

**The Clifton-Pohl torus**

It is the quotient of \(\mathbb{R}^2 \setminus \{(0, 0)\}\) endowed with the metric \(\frac{2dxdy}{x^2+y^2}\) by an homothety, usually \((x, y) \mapsto 2(x, y)\).

The radial field of \(\mathbb{R}^2\) induces a periodic Killing field on the torus.

A Lorentzian surface with a Killing field carries (at least) 3 natural foliations: the one given by the Killing field and the 2 lightlike one.

We will use these foliations in order to give a representation of the surface.
A picture of the CP-torus

Figure: The three foliations of the Clifton-Pohl plane
Incompleteness of the Clifton-Pohl torus

Proposition

1. The CP-torus is not geodesically complete (even if it is compact).
Incompleteness of the Clifton-Pohl torus

Proposition

1. The CP-torus is not geodesically complete (even if it is compact).
2. The CP-plane is extendable i.e. it can be isometrically embedded in a bigger surface (here it is a geodesically complete one).
Incompleteness of the Clifton-Pohl torus

Proposition

1. The CP-torus is not geodesically complete (even if it is compact).
2. The CP-plane is extendable i.e. it can be isometrically embedded in a bigger surface (here it is a geodesically complete one).

Proof: Let $F$ be the following simple change of variables:

$$F : ] - \pi/2, \pi/2[^2 \setminus \{0\} \to M$$

$$(u, v) \mapsto (\tan(u), \tan(v)) .$$

The metric $F^* g$ reads

$$2dudv \over \cos^2 u \sin^2 v + \sin^2 u \cos^2 v .$$

This metric extends to a metric $\hat{g}$ on $\mathbb{R}^2 \setminus \Lambda$. $\square$
The extended CP-plane
The extended CP-plane
With C. Boubel and C. Tarquini, we used the extended CP-plane in 2006 to construct an example of Lorentzian foliation which is equicontinuous on a proper open subset only.
With C. Boubel and C. Tarquini, we used the extended CP-plane in 2006 to construct an example of Lorentzian foliation which is equicontinuous on a proper open subset only.

More recently, with Ch. Bavard, we used it to prove a remarkable property of the CP-torus

**Theorem 1 (Bavard, M– (2013))**

*The CP-torus has no conjugate points.*

More recently, with Ch. Bavard, we used it to prove a remarkable property of the CP-torus

**Theorem 1 (Bavard, M– (2013))**

*The CP-torus has no conjugate points.*

- The extended CP-plane has many conjugate points.
- The CP-torus is not flat, so there is no (simple) Lorentzian Hopf Theorem.

The metric $\hat{g}$ is invariant under an action of $\mathbb{Z}^2$ and therefore gives a metric on a twice punctured torus. Its fundamental group can be seen as a Fuchsian group.
The universal cover of the extended plane
The properties of the CP-torus we saw are in fact quite general:

**Theorem 2 (Bavard, M– (2015))**

Let $T$ be smooth (resp. real analytic) Lorentzian 2-torus having a non trivial Killing field $K$. Then the universal cover of $T$ admits a smooth (resp. real analytic) lightlike complete extension $E$. In the real analytic case this extension is unique.
The properties of the CP-torus we saw are in fact quite general:

**Theorem 2 (Bavard, M– (2015))**

Let $T$ be smooth (resp. real analytic) Lorentzian 2-torus having a non trivial Killing field $K$. Then the universal cover of $T$ admits a smooth (resp. real analytic) lightlike complete extension $E$. In the real analytic case this extension is unique.

It is possible to obtain uniqueness in the smooth setting by asking the extension to have additional symmetries. When $K$ has no lightlike orbits, $T$ is geodesically complete and the extension is trivial.
The properties of the CP-torus we saw are in fact quite general:

**Theorem 2 (Bavard, M– (2015))**

Let $T$ be smooth (resp. real analytic) Lorentzian 2-torus having a non trivial Killing field $K$. Then the universal cover of $T$ admits a smooth (resp. real analytic) lightlike complete extension $E$. In the real analytic case this extension is unique.

We will say that $T$ is nonelementary if it is not flat and if $K$ has a lightlike orbit.
The properties of the CP-torus we saw are in fact quite general:

**Theorem 2 (Bavard, M– (2015))**

Let $T$ be smooth (resp. real analytic) Lorentzian 2-torus having a non trivial Killing field $K$. Then the universal cover of $T$ admits a smooth (resp. real analytic) lightlike complete extension $E$. In the real analytic case this extension is unique.

We will say that $T$ is nonelementary if it is not flat and if $K$ has a lightlike orbit.

**Theorem 3 (Bavard, M– (2015))**

If $T$ is real analytic and nonelementary then the exact sequence:

\[ 0 \to \mathbb{R} \cong \text{Isom}^0(E) \to \text{Isom}(E) \to \Pi \to 1 \]

is split.

Moreover, the action of $\Pi$ (through the choice of a section) on $E$ is conjugate to the action of a Fuchsian group on the hyperbolic space.
Universal extensions

Let $f : \mathbb{R} \to \mathbb{R}$ be a smooth function that vanishes somewhere. We will assume to simplify things that the connected components of $\mathbb{R} \setminus f^{-1}(0)$ do not cluster. We will say that $f$ is of finite type. We want to associate to $f$ a lightlike complete Lorentzian surface with a Killing field.
Let $f : \mathbb{R} \to \mathbb{R}$ be a smooth function that vanishes somewhere. We will assume to simplify things that the connected components of $\mathbb{R} \setminus f^{-1}(0)$ do not cluster. We will say that $f$ is of *finite type*. We want to associate to $f$ a lightlike complete Lorentzian surface with a Killing field.

We start with the Lorentzian surface $\text{Rib}_f = (\mathbb{R}^2, 2dx dy + f(x)dy^2)$. It has a Killing field $\partial_y$ but is not lightlike complete (because $f$ vanishes).

**Remark**

For any connected component $C$ of $\mathbb{R} \setminus f^{-1}(0)$ there exists a symmetry $\sigma_C$ of $C \times \mathbb{R}$ fixing a geodesic orthogonal to $K$ and permuting the lightlike foliations.
Let \( f : \mathbb{R} \to \mathbb{R} \) be a smooth function that vanishes somewhere. We will assume to simplify things that the connected components of \( \mathbb{R} \setminus f^{-1}(0) \) do not cluster. We will say that \( f \) is of \textit{finite type}.

We want to associate to \( f \) a lightlike complete Lorentzian surface with a Killing field.

We start with the Lorentzian surface \( \text{Rib}_f = (\mathbb{R}^2, 2dx dy + f(x)dy^2) \). It has a Killing field \( \partial_y \) but is not lightlike complete (because \( f \) vanishes).

**Remark**

For any connected component \( C \) of \( \mathbb{R} \setminus f^{-1}(0) \) there exists a symmetry \( \sigma_C \) of \( C \times \mathbb{R} \) fixing a geodesic orthogonal to \( K \) and permuting the lightlike foliations.

On \( C \times \mathbb{R} \) there exist coordinates \((u, v)\) such that the metric reads \( \pm du^2 + h(u)dv^2 \) and \( \sigma_C(u, v) = (u, -v) \).
The surface $X_f$

We take 2 copies of $\text{Rib}_f$ that we glue together thanks to the symmetries $\sigma_C$ (we choose one symmetry on each connected component). We obtain a (Hausdorff) Lorentzian surface $X_f$ which also has a Killing field $K$.

![Diagram](image-url)

**Figure:** The surface $X_f$

The surface $X_f$ is almost lightlike complete. The lightlike (i.e. the vertical and horizontal) orbits of $K$ may carry half complete geodesics. It is the case of the geodesics forming the red $T$. 
Addition of saddle points

To conclude the construction we take a 2-cover $Y_f$ of $X_f$ in order to transform each ”half saddle” (like the red T) into a punctured saddle.

For a good choice of gluing symmetries $\sigma_C$ the punctured saddles can be completed into saddles (i.e. we can add the blue point).

The surface obtained is now lightlike complete, we take its universal cover and call it the universal extension associated to $f$ and denote it $E_f^u$.

We obtain this way a lot of classical Lorentzian surfaces.
To conclude the construction we take a 2-cover $Y_f$ of $X_f$ in order to transform each "half saddle" (like the red T) into a punctured saddle.

The surface obtained is now lightlike complete, we take its universal cover and call it the universal extension associated to $f$ and denote it $E_f^u$. We obtain this way a lot of classical Lorentzian surfaces.
Link between $E^u_f$ and $\tilde{T}$

Theorem 2 is obtained by proving that there exists a function $f$ (not necessarily of finite type) such that $T$ is locally modeled on $E^u_f$ and that the associated developing map is injective. Theorem 3 is a special case of the following result about $\text{Isom}(E^u_f)$.

**Theorem 4**

Let $f : I \to \mathbb{R}$ be a smooth function and $E^u_f$ the associated extension. If $f''' \neq 0$ then the exact sequence:

$$0 \to \mathbb{R} \simeq \text{Isom}^0(E) \to \text{Isom}(E^u_f) \to \Pi \to 1$$

is split.

Moreover, the action of $\Pi$ (through the choice of a section) on $E^u_f$ is proper (and therefore conjugate to the action of a Fuchsian group on the hyperbolic space) if and only if $f$ is of finite type.
Some consequences

The spaces $E^u_f$ give a better understanding of the Lorentzian surfaces with Killing fields:

- By looking at the space of tori modeled on a given space $E^u_f$, we were able to give a complete classification of Lorentzian tori and Klein bottles with a Killing field.
- We know the universal cover of any non compact real analytic Lorentzian surface with a Killing field that satisfies a rather weak completeness condition.
- Maybe more anecdotally, we found a Lorentzian surface $S$ such that $\text{Isom}(S)$ is a 2-torsion group acting non properly on $S$.
- Thanks to this understanding, with Stefan Suhr, we gave three families of explicit examples of spacelike Zoll surfaces.
